Lecture-47
Perturbed Force: fz continued

Good morning friends, it must be tried of feeling be expression like the an it is again ask yourself what are you doing what are you doing we are try to developed mathematical model which will be using characteristic to at aeroplane it come of instable are not as fresh will as static stabilit.

As constant we have seen what conditions are but now you are do more generically we try to Develop equation of the motion and try to see that can I use this truth coming done stability the airplane I know very will dynamic stability in to the stability for the more cases and for an airplane.

(Refer Slide Time: 01:09)

It is very true and what was a approach the approach was we develop longitudinal to terminal perturbed equations of motion at what exactly will mean by that set ok. This is my airplane this is cruise by equilibrium right and about cruise I will giving the dispense small dispense and you try to see what happens we please understand the airplane is going like this and I cruise dispense

then but ok longitudinal case that has been this motion could have a this motion and the have this motion and there be a perturbation in pitching motion.

And it is derived at this motion and derived at a small q there is perturbation in the speed so In the derived at the small u the perturbation of the vertical velocity we denoted that by small w ok so u , q small w these are the particular of quantities and also we know that at this airplane is pitching like this and this like so pitching this there will be changing α we can't rate of change of α become is important z and also note down that α dot that playing important roll.

Important roll where if I try to find out f_x and f_z and the pitching movement is it because of the small disturbance this u there will there the perturbed u fracture of u fracture of q is will be there and perturbed then w component of the aircraft are be there I have will be there and also α dot will be there because you understand the body will just moving like this is introducing the α dot right.

The α will be jointing with in between the velocity vector in vertical component in the right so the α that also begin is doing like this as it doing like this is q α dot that what weight it is moving the α it is so it is how is that use it include α dot and then when said $f(u)$ ok and then q then of Couse there is δe also and α and α dot and δe move down here will be w but here it is α because you know α is nothing.

But w/u_1 so is there is w there will be α that is take this body like this if there is α perturbed α and there will be compound of this velocity it is w along z direction right during perturbation. Because we have which use stability axis which has steady states .that direction is fixed and the condition of steady states because whatever velocity vector of there.

The x axis there on the perturbed then there will be perturbation α what about the perturb α this perturb w that is compound along the z direction ok similarly here if I write $f(u)$, q , α , α dot, δe and u , q , α , α dot, δe and one more thing you realize please you note that all your lecture put not α dot will explain you will so approximation but

coming back the you understand that will want to ensure these arguments are non-dimensional that write we said inset of u.

We will write on u/u_1 is set of q , we will write $q u / 2 u_1$ the It set of α dot will write the α dot $c / z u$ look at their non-dimensional ok all on the non-dimensional is in similarly here again u / u_1 $q u / 2 u_1$ α dot was α dot $c / 2 u_1$ similarly to get u / u_1 this is $q c / 2 u_1$ α dot $c / 2 v$ one simply q α dot they have dimensional radians per second right ok fine once we agree to this and we made this apposition that was a normal airplane the small dispense I may eliminate α dot $z u$ one effect on effects for most of their airplane.

(Refer Slide Time: 06:12)

q, α

$$f_x = f\left(\frac{u}{u_1}, \left(\frac{q}{c}\right) \alpha, \delta_e\right)$$

$$p_x = f\left(\frac{u}{u_1}, \alpha, \delta_e\right)$$

$$\delta f_x = \frac{\partial F_{xA}}{\partial (u/u_1)} \frac{u}{u_1} + \frac{\partial F_{xA}}{\partial \alpha} \alpha + \frac{\partial F_{xA}}{\partial \delta_e} \delta_e$$

So we wrote f_x is equal to function of u / u_1 then $q c / 2 u_1$ α and δe right again file there are normal condition airplane will see by experience and this effective also not that much but I know understand that is effect is because of q and what is he effect of α dot we will discussing this thing today also right but this point of time the assuming that these effect also cut terminate f_x wrote as f function of u / u_1 α and δe ok and then we wrote the expand it $\delta f_x = d f_x / d (u / u_1)$ and u / u_1 plus $d f_x / d \alpha$.

α plus $d f_x / d \delta e$ by δe by δe and right this is the f_x . What is f_x this the perturbed aerodynamically force and then we know how to valuated this it. You are very clear was at the evaluate and steady state and we have derive the expression and then no explicitly what is the

from of f x right that will be done ok I note down here this q and alpha dot was a we need a attention we will need the distraction we will go for that similar think we need for f x ok here although the first lecture we need the lecture liked as I have eliminated the alpha dot like to u1 let us skip it so all so get someone fell.

what is happening remember alpha dot will has no effect on f z it will serve another then or right although for all airplane most the airplane we made still in this but just see you that handling with handing alpha dot derivate I will keeping with assume movement with consent u/ u1 q very important because you know that c m q it will very very important diversity from the dynamical stability point of you alpha and there is alpha dot c that is will be very important delta e.

(Refer Slide Time: 09:01)

The image shows a chalkboard with the following handwritten equation for longitudinal perturbations:

$$f_z = \frac{\partial F_{zA}}{\partial u_1} \frac{u}{u_1} + \frac{\partial F_{zA}}{\partial \alpha} \alpha + \frac{\partial F_{zA}}{\partial qc} \frac{qc}{2u_1} + \frac{\partial F_{zA}}{\partial \dot{\alpha}} \frac{\dot{\alpha}}{2u_1} + \frac{\partial F_{zA}}{\partial \delta e} \delta e$$

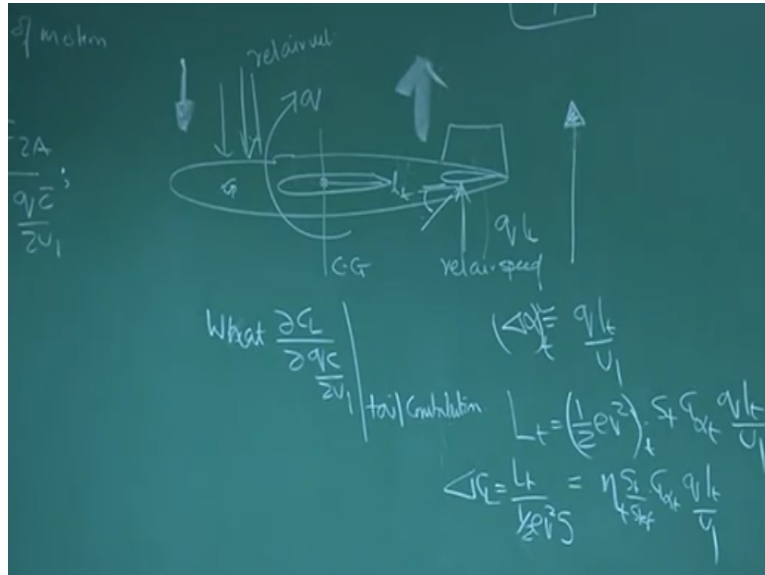

So it will be developing expression for although derivative ability now still yesterday when we find use the f z what is the dame is not mistaken every time fx is equal to d f z a/d u/u1 and u /u1 plus d f z a/ plus d alpha and alpha plus d f z a / d q c / 2 u1 and q c /2 u1 plus now we adding d f z a/ d alpha dot c as / a u on alpha c / 2 u1 plus d f z a / d delta e int delta e so we had assuming that f x the function of u and qc and alpha and alpha dot and delta e right.

I would to talk the alpha dot in the last lecture like to last exit now you are relaxing is expanding now we are become comfortably handle this we find to know fx it know. So what is the expression of d f z / d u by u1 which have been done what is the d f z The with by d e u by alpha

we have done we have just check for this one this one this also already done we have the last lecture the today first.

Will do the $\frac{dF_z}{dq}$ by the $\frac{dC_L}{dq}$ by u_1 and $\frac{dF_z}{dq}$ by $\frac{d\alpha}{dq}$ $2 u_1$ ok let us focus on that it I have all on already mention.

(Refer Slide Time: 10:36)

On all the $\frac{dF_z}{dq}$ by $\frac{dC_L}{dq}$ by u_1 but let see the revisit again let us check this is airplane this is airplane ok and this is tail and here the wing and let see this the cg of the airplane right what we are try to find out. We try to find out what is the parceled derivative $\frac{dF_z}{dq}$ and $\frac{dC_L}{dq}$ and $\frac{d\alpha}{dq}$ of course $\frac{dC_L}{dq}$ by $2 u_1$ and non-dimensional the base on.

The sitting is if I give the positive q why that there will be change In the force in the z direction ok for a small perturbed frozen now I see if I give a perturbation q is a small q what to happen this will be go down so there q into L_t in the relative speed right similarly as this is the cg so this position is going down so there will be also and some set of a and relative the velocity this position also this position also and of cg and could see one thing as it goes down there is force cl and additional cl is come the vertical direction

Which will purpose in to q and as it is going to up there will be sound force is coming down like this right but for airplane this position is predominant the force is consider this and this ok what

will do now because you understand and the another thing this l_t is find larger the ok compare to any center of pressure if I take for the what every force pressure distribution is because of q this length is smaller compare to his and this is not that lifting as compare to the tail so tail will be more the tail α so natural that force will be more and if I want to just check.

What is d_{cl} by $q u_1$ just take the is tail contribution because we are assuming that the tail contribution is more significant same cent for the contribution ok how to I find out so very simple because of q what is the $\delta \alpha$ at tail additional it is $q l_t$ by u_1 approximately righty what is force and the tail and the l tail will be $\frac{1}{2} \rho v^2$ at tail into S_{tail} and cl_{α} tail into α the α is $q l_t$ by u_1 ok .

So then we are expect now what is δc_l . the δc_l is will be l_t by $\frac{1}{2} \rho v^2$ into f reference so this will become Neeta tail l is still now s reference into cl_{α} tail into $q l_t$ by u_1 and what will be signed we could see that is going down like this it is like to α in to is positive so δc_l will be the lift direction so as for the conversion that is the leave direction is opposite to the z direction right for the small α so whatever you get here right it remember cl is consider in positive.

Why will be transfer in it in to z direction there is become negative we will watch out for that ok

(Refer Slide Time: 14:39)

$$C_{Lq} = \frac{\Delta C_L}{\frac{q_c}{2v_1}} = \eta \frac{s_t}{s} \cdot C_{L\alpha} \frac{q_c}{v_1}$$

Now for this is C_L so we have a ΔC_L is equal to ηs_t by s reference into $C_L \alpha$ tail and q_c by v_1 and you know $d C_L$ by $d q_c$ by $2 v_1$. We find out see it a linear everything is linear so I simply can write $C_L q_c$ this divide by the q_c by $2 v_1$ and that will be q_c by $2 v_1$ for U_1 , U_1 is cancel q_c by q_c cancel so I get $d C_L$ by $d q_c$ and C_L by $2 v_1$ is equal to two ηs_t by s reference with wing $C_L \alpha$ tail then l_t by c ok.

Could it check here q and q will be canceled so ηs_t exceeded s $C_L \alpha$ tail l_t by the c bar and two both upwards this is the expression for C_{Lq} ok.

(Refer Slide Time: 15:49)

longitudinal perturbed Eqn

$$C_{mq} = ? \frac{\Delta C_m}{\frac{\partial q_c}{\partial v_1}} = ?$$

$$C_{mq} = -\frac{l_t}{c} \cdot 2 \eta \frac{s_t}{s} \cdot C_{L\alpha} \left(\frac{l_t}{c}\right)$$

$$C_{mq} = -2 \eta \frac{s_t}{s} \left(\frac{l_t}{c}\right)^2 C_{L\alpha}$$

$$C_{Lq} = \frac{\partial C_L}{\partial q_c} = 2 \eta \frac{s_t}{s} \cdot C_{L\alpha} \left(\frac{l_t}{c}\right)$$

$$\Delta C_L = C_{Lq} \left(\frac{q_c}{2v_1}\right)$$

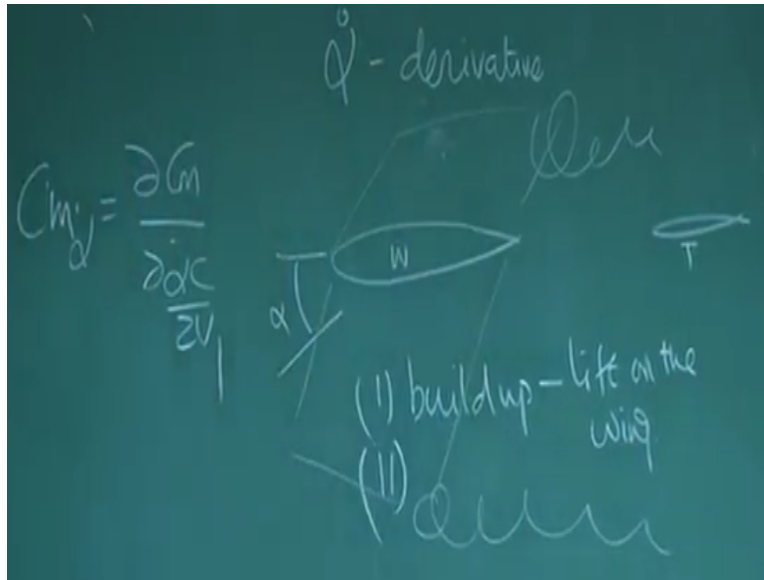

This is the expression for the \dot{c}_l if are and they find how much δc will be coming because of q what should be answer it is the \dot{c}_l and q \dot{c}_l by q u_1 that is we understand it is not \dot{c}_l into q because the \dot{c}_l will depend the as $d \dot{c}_l$ by $d q$ c by c^2 that is the important ok this is the understood \dot{c}_l now we not leave it here we also at for completion what will do at we it at one we did we also try to see what is see in what is c_m q this will come ok.

This is the pitching movement changing the pitching movement because of q and like to change the c because of q this is also changing of the c_m by $d q$ c by $2 u_1$ ok. So let us derive the expression we all come to close to force movement is simple so what will be c_m q . c_m q will be nothing but minus l t into c into \dot{c}_l q that is two Neeta at still by s reference and \dot{c}_l alpha tail into l t by c right this is \dot{c}_l q simple we find to do example this is the δl into l t .

In the movement we tail and sure and that is should be minus \sin . Why put the minus \sin because the positive tail will be negative pitching movement and \sin conversion are from as right so you when get expressions of the $d m$ q as minus two , two Neeta s t by s it is l t by c whole square right to the \dot{c}_l alpha t and of course the minus \sin write correctly minus two theta s t by s and l t by c also so we know the expression of $d m$ q you know the expression of \dot{c}_l q .

The \dot{c}_l q right is negative that is very well now it is could be c g and this is the tail if I am giving the q like this so it is going down the negative value will be there the δc_l will be there the δc_l will be give movement about c g notes down that is the this the minus and this here and we have known what is expression \dot{c}_l q and \dot{c}_l q will be try to know the expression for the \dot{c}_l alpha dot and c_m alpha dot and I have done come back to the perturbed equation.

(Refer Slide Time: 18:43)

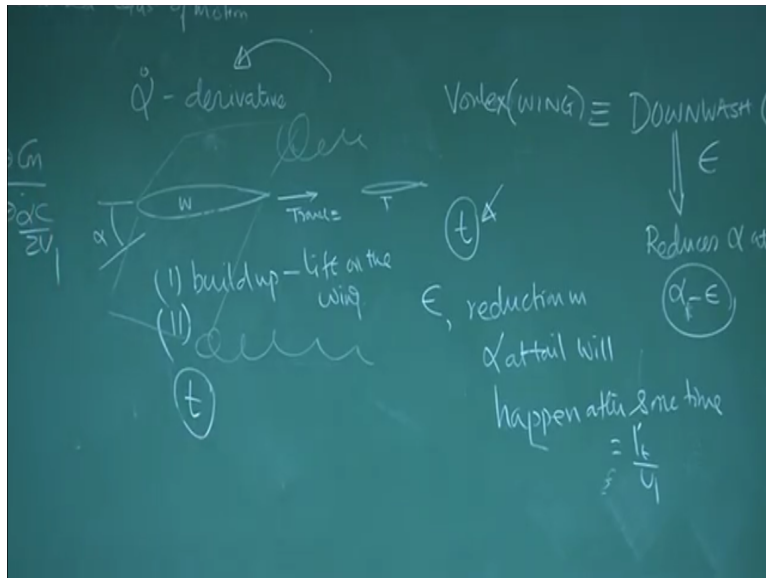

We have understood $C_m q$ and $C_l q$ it is done. now we are focus of $C_m \alpha \dot{q}$ and you know the $C_l \alpha$ by definition $d C_l$ by $d \alpha$ dot by $2 u_1$ and $C_m \alpha \dot{q}$ is equal to $d C_m$ by $d \alpha$ dot C by $2 u_1$ and you know why this $C u^2 u_1$ because the α dot the dimensional to converter to the non-convertible the dimensional quality and these are the text book are the covered and the α dot derivative right.

Let understand one thing very fundamental if this the wing ok and this is the tail. Wing and tail as the airplane seen the α in this the perturbed α please understand it doesn't lift develop list it take time to build the lift distribution understood this why you understood this if is α lift $C_l \alpha$ into α but it is text time.

Text time to buildup lift so the time component and so the second time so I right buildup of lift on the wing and text book they also take about in diesel lift right the second is very important you remember the because of the final of the right they will be traveling like this they introduce downers at the tail they introduce the tail so what is this for text this is wing from wing introduces.

(Refer Slide Time: 20:47)

They introduce downwash at the deal vertices or vortex which is introduces downwash at (tail) right and what are this to this downwash epsilon it reduces alpha at the tail right so something alpha t -or alpha1-epsilon so get reduced no good see that if there is time component in epsilon right it is not that something fix them word it is changing with time then the angle at the tag the tail also becomes function of time ok

We will at steady state but you have be careful and give this statement what I meaning is please understand this vertices will travel right approximately to the speed of the air craft there are device there are this 50%speed but I assuming that travels same speed of the air plane so that means suppose analyzing the time t right what is happening at time t. the epsilon reduction will not sink of the plane because epsilon reduction in alpha in alpha will at tail will happen when will happen after some time .

Because what is this will travel of the sometime at the tail then all the downwash angle will be seen at the tail at the time t that means what is happening how much time will take roughly $\frac{l_t}{u_1}$ it is the dc from the at the tail dc of the wing to dc of the tail. I call you l t frank it is the distance between the cg of the airplane and ac of the tail and ac of the wings to ac of the tail to be the both size. So what is happening what is the understanding if I am looking at the time to then the downwash seen by the tail will happen later at time.

L t/u1 if that the time the downwash does not wing starts if I start thinking at time to the what is the generator from the wing at the time to this effect have not been by fell by the tail correct that means and I am analyzing for a time t. this is actually sing the more angle it is not see the epsilon that more angle Give me a downward movement pitching movement and that is an alpha dot the force is a cl alpha dot it is clear please understand hear I am focusing the phenomena at the time t at time t angle of the what is angle of the wing at what is the angle m of the tail.

At the time t is what is it be generated but it will take around lt prime u1 time to each tail to downwash correct that we have time to that always effect t is not seen by the tail. The tail has more angle effected correct reduced angle only after time l t/u1 so at a time t is analyzing it is actually practically have a more angle effected then what a thinking minus epsilon that more angle effected all pitching movement down on force upward this is will be upset cl alpha dot and this is movement will be associate to cm alpha dot . It is the physics.

(Refer Slide Time: 25:14)

$$\Delta PM = -C_{L\alpha} \left(\frac{d\epsilon}{d\alpha} \right) \dot{x} \left(\frac{l_t}{u_1} \right) q S_t l_t$$

$$C_{m\dot{\alpha}} \equiv \text{lag in downwash effect.}$$

$$\Delta \alpha = \frac{d\alpha}{dt} \Delta t = \frac{d\alpha}{dt} \left(\frac{l_t}{u_1} \right)$$

$$\Delta x = \Delta \epsilon = \left(\frac{d\epsilon}{d\alpha} \right) \Delta \alpha = \left(\frac{d\epsilon}{d\alpha} \right) \dot{x} \left(\frac{l_t}{u_1} \right)$$

Let us how to develop the model. Ok we discuss this second monkey path I know there will be confusion doesn't matter we again discuss this things monkey path .

(Refer Slide Time:25:14)

$C_{m\dot{\alpha}} \equiv \text{lag in downwash effect.}$

$$\Delta PM = -C_l \left(\frac{d\epsilon}{d\alpha} \right) \dot{\alpha} \left(\frac{L}{U_1} \right) \frac{1}{2} \rho S_{tail} k$$

$$\Delta \alpha = \frac{d\alpha}{dt} \Delta t = \frac{d\alpha}{dt} \left(\frac{L}{U_1} \right)$$

$$\Delta \alpha = \Delta \epsilon = \left(\frac{d\epsilon}{d\alpha} \right) \dot{\alpha} = \left(\frac{d\epsilon}{d\alpha} \right) \dot{\alpha} \left(\frac{L}{U_1} \right)$$

$$\Delta C_m = \frac{\Delta PM}{\frac{1}{2} \rho U_1^2 S_{tail} k}$$

$$\Delta C_m = -\frac{1}{2} \rho U_1^2 S_{tail} k \left(\frac{d\epsilon}{d\alpha} \right) \dot{\alpha} \left(\frac{L}{U_1} \right)$$

$$L = \left(\frac{1}{2} \rho U_1^2 \right) S_{tail} k \Delta C_m$$

So $C_m \alpha \dot{\alpha}$ is genuinely term us take =lag in downwash effect you understand what is why this lag is they because at the time t when the we focusing at the wing then its text time it will by you be downwards want to reach the take the downwash.

So there is the lag and downwash is the lag. ok you know $\Delta \alpha = d\alpha/dt \Delta t = d\alpha/dt L/U_1$ right and what is $\Delta \epsilon = d\epsilon/d\alpha \Delta \alpha = d\epsilon/d\alpha \dot{\alpha} L/U_1$ right so this $\Delta \epsilon$ the angel of tag this more by this actually because this actual this happen you see $\Delta \epsilon$ of the angel which will be realize the till only after the time L/U_1 and at the time t this is the extra angle you got so I will write pitching moment and Δ pitching moment.

And as minus $C_l \alpha \dot{\alpha} d\epsilon/d\alpha \dot{\alpha} L/U_1 C_l \alpha$ into α this is because there is the angle it a more at the tail because that downwash has not reach what is the reach the downwash .angle vector is more than this much and this into q_{tail} and $v_{tail}^2 S_{tail}$ and L will we the pitching moment is in it half row $v_{tail}^2 S_{tail} C_l \alpha$ into α into momentum there is the pitching movement.

No problem I will explain ΔC_m what ΔC_m will be Δ pitching movement divide by half row $v_{tail}^2 S_{tail} k$.the ΔC_m will be Δ pitching movement into half row $v_{tail}^2 S_{tail} k$ if

you do that what will happen. V is nothing but $u \cdot \Delta c m = -n t s t/s s c \text{ bar}$ is $(lt/c \text{ bar})$ and of course you have $cl \alpha$ tail.

$D \epsilon / d \alpha$ $\alpha \dot{l} t / u_1$ right let us check .this is pitching moment divided by half eu_1 square $sc \text{ bar}$ so half row eu_1 square q till and n till the ratio $s t$ by s and lt by $c \text{ bar}$. Taken here lt/c_1 taken here now what is happening the left will $d \alpha$ and α is here right what is $cm \alpha \dot{\alpha}$.

(Refer Slide Time: 29:05)

$$\Delta C_m = - \frac{1}{2} \left(\frac{S_t}{l} \frac{l}{c} \right) C_{\alpha t} \left(\frac{d\epsilon}{d\alpha} \right) \dot{\alpha} \frac{l}{c}$$

$$C_{\alpha t} = \frac{\Delta C_m}{\dot{\alpha} \frac{l}{c}}$$

$$C_{\alpha t} = -2 \frac{1}{2} \left(\frac{S_t}{l} \frac{l}{c} \right)^2 \left(\frac{d\epsilon}{d\alpha} \right)$$

$\Delta c m$ is equal to minus $N eeta s t/s lt/c$ right so what is $cl \alpha$ till $d \epsilon / d \alpha$ $\alpha \dot{\alpha}$ (lt/u_1) then $cm \alpha \dot{\alpha}$ is nothing but $= \Delta c m / \alpha \dot{\alpha} c / zu_1$ so there is slope so if I divided by $\alpha \dot{\alpha} c / zu_1$ what will get will get $cm \alpha \dot{\alpha} = u_1$ will go. First of all $\alpha \dot{\alpha} t$ and $\alpha \dot{\alpha}$ is go and $2 N eeta s t/s lt/c$ whole square lt here $c \text{ bar}$ is here $cl \alpha t d \epsilon / d \alpha$ ok .this is expression for $c \alpha \dot{\alpha}$ how to $\alpha \dot{\alpha} t$ you know what you mean $d \epsilon / d \alpha$ dot those we simplify that the expression also get impartial charge ok.

You will understand that $cm \alpha \dot{\alpha}$ you can easily say. If you just for the force generated $.d$ axel an and $d \alpha$ low speed simplify the expression also be the empirical charge for that ok so we understand what is $cl \alpha \dot{\alpha}$ so you can easily to see $cl \alpha \dot{\alpha}$ just you how much is the force generator ok that that matter. I will leave with you .you try to find out expression for $cl \alpha \dot{\alpha}$ ok clear.

Very simple delta epsilon is the left equal to find lift. Lift is equal to half rho v square as till s till
cl alpha till epsilon delta epsilon this is expression with given by this then follow the definition
of cl alpha dot and find it ok .i expect you will do this, thanks.
