Lecture – 02
Linear solvers – II

So, welcome to the lectures of this Finite Volume Method. Now, if you put these things back in the algorithm what will happen?

(Refer Slide Time: 00:21)

Solution of linear systems

Algorithm:

$$u_{ij} = a_{ij} \quad ; j = 1 \text{ to } N$$

$$l_{i1} = \frac{a_{i1}}{u_{11}} \quad , i = 2 \text{ to } N$$

for $i = 2 \text{ to } N-1$

$$u_{ij} = a_{ij} - \sum_{k=1}^{i-1} l_{ik} u_{kj} \quad ; j = i, i+1, \dots, N$$

$$l_{ki} = \frac{a_{ki}}{u_{ii}} - \sum_{j=1}^{i-1} l_{kj} u_{ji} \quad ; k = i+1, i+2, \dots, N$$

}

$$u_{NN} = a_{NN} - \sum_{i=1}^{N-1} l_{Ni} u_{iN}$$

$A \Rightarrow LU$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR
Ashoke De 92

So, first thing that I will have u_{1j} equals to a_{1j} for which j goes from 1 to N ; then I get l_{i1} equals to a_{i1} by u_{11} where, i goes from 2 to N . So, these two elements initially are being computed and then you go over loop for i goes 2 to N minus 1. Then u_{ij} equals to a_{ij} minus k equal to 1 to i minus 1 $l_{ik} u_{kj}$ where, j goes from i plus 1 so on N . And, the lower triangular system is a_{ki} minus summation of j equals to 1 to i minus 1 $l_{kj} u_{ji}$ where k goes from i plus 1 i plus 2 so on N .

So, that is were the loop closes and finally, you get u_{NN} equals to a_{NN} minus i goes to N minus 1 $l_{Ni} u_{iN}$. So, that is how the whole algorithm works. Then you obtain from A getting decomposed into 2 component lower and upper triangular system and once you get that then you have to get the solution for that. So, now the steps which are required is the substitution step ok.

(Refer Slide Time: 02:43)

Solution of linear systems

Substitution Step $A = LU$

Need to calculate the vector 'c' : forward substitution

1st } $C_1 = b_1$
 $C_i = b_i - \sum_{j=1}^{i-1} L_{ij} C_j \quad i = 2, 3, \dots, N$

Get the value of ϕ : back substitution

2nd } $\phi_N = \frac{C_N}{U_{NN}}$
 $\phi_i = \frac{C_i - \sum_{j=i+1}^N U_{ij} \phi_j}{U_{ii}} \quad i = N-1, N-2, \dots, 2, 1$

~~$A \rightarrow LU = b$~~ : # of operation : $\approx \frac{2N^3}{3}$
($N \times N$)

INDIAN INSTITUTE OF TECHNOLOGY KANPUR
Ashoke De 93

So, now my A got into L and U, one is lower and upper triangular system and first need to calculate the vector c. So, that through forward substitution process where, you get C_1 equals to b_1 and C_i equals to b_i minus $\sum_{j=1}^{i-1} L_{ij} C_j$ where, goes to 2 3 to N. So, that is where you get the and the next step you get the values of phi by back substitution process, which will be ϕ_N equals to C_N divided by U_{NN} . And, ϕ_i equals to C_i minus $\sum_{j=i+1}^N U_{ij} \phi_j$ divided by U_{ii} . So, where i goes N minus 1 N minus 2 to 2 1 like that.

So, initially 1st step this is your first step where, you get the forward substitution to get the vector C and the 2nd step you do the backward substitution to get the. So, essentially you had A equals to LU and where this was solved for b and it was written $LU c$ equals to b and from there you get the solution Now, that important points are few here like the elements of this L and U can be directly stored in the matrix A; if it is no longer needed. This is because that A are only needed when the corresponding elements of either L or U are calculated.

So, the number of operation required to perform here, the number of operation which were required to perform for LU factorization for a system of N by N is 2 something N cube by 3 . So, which is double the operation that is required to solve through the gauss elimination process again the advantage of this LU factorization is that when the same matrix A applies to different b, then know need to calculate L and U factorizations again

and again, the coefficients just can be directly applied to. So, which makes the solver more efficient.

(Refer Slide Time: 06:39)

Solution of linear systems

LU decomposition by Gauss Elimination (Algorithm)

```

$$u_{ij} = a_{ij} \quad ; \quad j=1 \text{ to } N$$

for  $k=1$  to  $N-1$ 
  {
    for  $i= k+1$  to  $N$ 
      {
        
$$l_{ik} = \frac{a_{ik}}{a_{kk}}$$

        {
          for  $j= k+1$  to  $N$ 
            
$$u_{ij} = a_{ij} - l_{ik} * a_{kj}$$

          }
        }
      }
    }
  
```

INDIAN INSTITUTE OF TECHNOLOGY KANPUR
Ashoke De 94

Now, one can obtain this LU factorization through Gauss elimination process. So, LU decomposition by Gauss elimination that is another way of obtaining the thing and so, this is sometimes can be also used in some CFD codes. Now, if you look at that algorithm, how you do that you have simple u_{1j} equals to a_{1j} where, j goes from 1 to N . Now, you go over loop for k equals to 1 to N minus 1 you obtain i equals to k plus 1 to N where, l_{ik} equals to a_{ik} divided by a_{kk} .

And, then here you start then you get for j goes from k plus 1 to N u_{ij} equals to a_{ij} minus l_{ik} multiplied with a_{kj} . Then you close that loop which will get you this information and then the upper one and the last one. So, that is where the Gauss elimination process can be also used. Now, the important points. So, this is possible all these Gauss elimination or LU factorizations when you have generic.

(Refer Slide Time: 08:41)

Solution of linear systems

Direct approach for Banded sparse Matrices | $A\phi = b$

(a) Tri Diagonal Matrix Algorithm (TDMA) 

$$a_i \phi_i + b_i \phi_{i+1} + c_i \phi_{i-1} = d_i, \quad i = 1, 2, \dots, N,$$

$c_1 = b_N = 0$

For $i=1$, $a_1 \phi_1 = -b_1 \phi_2 + d_1 \Rightarrow \phi_1 = \frac{-b_1}{a_1} \phi_2 + \frac{d_1}{a_1}$

For $i=2$, $a_2 \phi_2 = -b_2 \phi_3 - c_2 \phi_1 + d_2$

$$\Rightarrow \phi_2 = \frac{-a_1 b_2}{a_1 a_2 - c_2 b_1} \phi_3 + \frac{d_2 a_1 - c_2 d_1}{a_1 a_2 - c_2 b_1}$$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR
Ashoke De 95

Now, one can look at this method for or other the direct approach for banded sparse matrices. So, this should be very specific case because, what we have discuss so for is in more generic approach because irrespective of what is the property of A; we did the Gauss elimination or we could do the LU factorization. Now, when you say that the banded sparse matrices; that means, the matrix A which is sitting here it could be looking either some sort of a band like that or some sort of a band like that. Or so, the solvers which can be used for this case cannot be generalized for the elimination process.

In this category the first one which we will talk about is the Tri Diagonal Matrix Algorithm which is called TDMA. And, what happens this algorithm is known as the Thomas algorithm and it is a very common and old algorithm which was I mean or other often discussed in any CFD, but it has some specific application for a particular banded system like tridiagonal system; this is one of the efficient solver. How you get it? Let us say you consider this cell like that starts from i you have 2 1 3 4 these are the points and so on you get N N minus 1. So, number of points N and then the cell centers value.

So, the coefficient matrix for this kind of system if one has to write $a_i \phi_i + b_i \phi_{i+1} + c_i \phi_{i-1} = d_i$, where i goes from 1 2 dot dot on N c 1 0. So, what one can do for i equals to 1 you can directly solve this equation $a_1 \phi_1 = -b_1 \phi_2 + d_1$ which you can see ϕ_1 can be solved minus b_1 by a_1 by ϕ_2 plus d_1 by a_1 .

Similarly, for $i \geq 2$ if one has to write you will get $a_i \phi_i = -b_i \phi_{i+1} + c_i \phi_{i-1} + d_i$ which will get you the equation for ϕ_i which is $-\frac{b_i}{a_i + c_i P_{i-1}} \phi_{i+1} + \frac{d_i - c_i Q_{i-1}}{a_i + c_i P_{i-1}}$.

(Refer Slide Time: 12:47)

Solution of linear systems

$$\phi_i = P_i \phi_{i+1} + Q_i$$

$i = 1, 2, \dots, N$

$$\left. \begin{aligned} \phi_{i-1} &= P_{i-1} \phi_i + Q_{i-1} \\ a_i \phi_i + b_i \phi_{i+1} + c_i \phi_{i-1} &= d_i \end{aligned} \right\} \Rightarrow \phi_i = \frac{b_i}{a_i + c_i P_{i-1}} \phi_{i+1} + \frac{d_i - c_i Q_{i-1}}{a_i + c_i P_{i-1}}$$

$$\left. \begin{aligned} P_i &= -\frac{b_i}{a_i + c_i P_{i-1}} \\ Q_i &= \frac{d_i - c_i Q_{i-1}}{a_i + c_i P_{i-1}} \end{aligned} \right\} \quad i = 1, 2, \dots, N$$

$$\left. \begin{aligned} \text{for } i=1, \quad P_1 &= -\frac{b_1}{a_1}, \quad Q_1 = \frac{d_1}{a_1} \\ \text{For } i=N, \quad b_N &= 0 \\ P_N &= 0, \quad \phi_N = Q_N \end{aligned} \right\}$$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR

Ashoke De 96

So, if one generalize this then one can write $\phi_i = P_i \phi_{i+1} + Q_i$. So, that is the generic formula for any i , where i goes from 1 to $2N$. Now, if you combine with the equation $i+1$ then $\phi_{i-1} = P_{i-1} \phi_i + Q_{i-1}$ $a_i \phi_i + b_i \phi_{i+1} + c_i \phi_{i-1} = d_i$. So, from here you get $\phi_i = \frac{b_i}{a_i + c_i P_{i-1}} \phi_{i+1} + \frac{d_i - c_i Q_{i-1}}{a_i + c_i P_{i-1}}$. So, that is what you get. Now, if you compare this one and the previous one you can see that P_i is nothing, but b_i divided by $a_i + c_i P_{i-1}$.

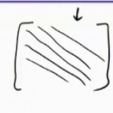

And, Q_i is $\frac{d_i - c_i Q_{i-1}}{a_i + c_i P_{i-1}}$. In both these cases i goes from 1 to N . Now, for $i=1$ you can get $P_1 = -\frac{b_1}{a_1}$ and $Q_1 = \frac{d_1}{a_1}$. And, similarly for $i=N$ you get since, $b_N = 0$ you get $P_N = 0$ $\phi_N = Q_N$. So, that is how the algorithm works actually for a system like that you can, if you put in the algorithm then it would be quite handy for this kind of banded system.

(Refer Slide Time: 15:35)

Solution of linear systems

Penta-Diagonal Matrix Algorithm (PDMA) $A\phi = b$

$$a_i \phi_i + b_i \phi_{i+2} + c_i \phi_{i+1} + d_i \phi_{i-1} + e_i \phi_{i-2} = f_i$$

($i = 1, 2, \dots, N$)

subject to:

$$d_1 = e_1 = e_2 = 0$$

$$b_{N-1} = b_N = c_N = 0$$

for $i=1$:

$$\phi_1 = -\frac{b_1}{a_1} \phi_3 - \frac{c_1}{a_1} \phi_2 + \frac{f_1}{a_1}$$

for $i=2$:

$$\phi_2 = -\frac{c_1 b_2}{c_1 a_2 - d_2 c_1} \phi_4 - \frac{c_1 c_2 - b_2 d_2}{c_1 a_2 - d_2 c_1} \phi_3 + \frac{a_1 f_2 - d_2 f_1}{c_1 a_2 - d_2 c_1}$$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR

Ashoke De 97

Now, the second one which could be also of interesting is the penta diagonal Penta Diagonal Matrix Algorithm, which actually talks about PDMA. Previous one was the TDMA, this case call the PDMA and again this one you get; see the TDMA one can obtain if somebody discretize the diffusion equation in 1 dimension. Now, when someone discretize the diffusion equation in 2 dimensional system, he gets essentially this kind of a penta diagonal system; that means, not 3 you have 5 banded system. So, this is called the penta diagonal system and in 2 dimensional the diffusion equation discretization can lead to this kind of situation. Now, once you get this kind of PDMA so, you can have a very specific solver which can actually be used for this kind of solution.

And, if one uses the notation very standard notation and like the one which we have used here, the i goes from 1 to N then the equation system for penta diagonal system would be $a_i \phi_i + b_i \phi_{i+2} + c_i \phi_{i+1} + d_i \phi_{i-1} + e_i \phi_{i-2} = f_i$, where i goes 1 2 to N . If you see the base variable at i th it is equally distributed between $i+1$ $i-1$ $i+2$ $i-2$ and there are coefficients associated with it.

So, this is the equation which has the 5 points $i+1$ $i+2$ $i-1$ $i-2$ that leads to a penta diagonal system. This is called the 5 points tensile and which is this particular one is subjected to $d_1 = e_1 = e_2 = 0$ and $b_{N-1} = b_N = c_N = 0$. So, it has very specific system. Now, if you

write for i equals to 1, this particular 1 it gives you back ϕ_1 equals to $\frac{-b_1}{a_1}$ by ϕ_3 minus c_1 by a_1 ϕ_2 plus f_1 by a_1 .

Now, similarly for i equals to 2 the ϕ_2 can be obtained $\frac{-a_1 b_2}{a_1 a_2}$ minus $d_2 c_1$ minus. So, this is multiplied by ϕ_4 minus $a_1 c_2$ minus $b_1 d_2$ divided by $a_1 a_2$ minus $d_2 c_1$ ϕ_3 plus $a_1 f_2$ minus $d_2 f_1$ by $a_1 a_2$ minus $b_2 c_1$. So, this essentially you put the values of i in this equation and then you start obtaining individual once. So, this way one can proceed then you can write an generic expression for ϕ_i .

(Refer Slide Time: 20:17)

Solution of linear systems

Generic form: $\Rightarrow \boxed{\phi_i = P_i \phi_{i+2} + Q_i \phi_{i+1} + R_i} \quad i=1, 2, \dots, N$

ϕ_{i-1} & ϕ_{i-2} using this eqn \curvearrowright

$$\Rightarrow \phi_i = \frac{-b_i}{a_i + e_i P_{i-2} + (d_i + e_i Q_{i-2}) Q_{i-1}} \phi_{i+2} - \frac{c_i + (d_i + e_i Q_{i-2}) P_{i-1}}{a_i + e_i P_{i-2} + (d_i + e_i Q_{i-2}) Q_{i-1}} \phi_{i+1} + \frac{f_i - e_i R_{i-2} - (d_i + e_i Q_{i-2}) R_{i-1}}{a_i + e_i P_{i-2} + (d_i + e_i Q_{i-2}) Q_{i-1}}$$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 98

So, in generalized form or rather generic form one can write that ϕ_i equals to $P_i \phi_{i+2}$ plus $Q_i \phi_{i+1}$ plus R_i . So, which goes for a loop i equals to 1 to N . Now, you compute ϕ_{i-1} and ϕ_{i-2} using this equation. So, essentially using this you compute that and then from there you obtain ϕ_i equals to $\frac{-b_i}{a_i}$ minus. So, with minus sign sitting there $\frac{-b_i}{a_i + e_i P_{i-2} + (d_i + e_i Q_{i-2}) Q_{i-1}}$ ϕ_{i+2} plus $\frac{-c_i + (d_i + e_i Q_{i-2}) P_{i-1}}{a_i + e_i P_{i-2} + (d_i + e_i Q_{i-2}) Q_{i-1}}$ ϕ_{i+1} plus $\frac{f_i - e_i R_{i-2} - (d_i + e_i Q_{i-2}) R_{i-1}}{a_i + e_i P_{i-2} + (d_i + e_i Q_{i-2}) Q_{i-1}}$. So, that is the first term.

And, the second term would be $\frac{-c_i + (d_i + e_i Q_{i-2}) P_{i-1}}{a_i + e_i P_{i-2} + (d_i + e_i Q_{i-2}) Q_{i-1}}$ ϕ_{i+1} plus $\frac{f_i - e_i R_{i-2} - (d_i + e_i Q_{i-2}) R_{i-1}}{a_i + e_i P_{i-2} + (d_i + e_i Q_{i-2}) Q_{i-1}}$. So, you get an generic expression for ϕ_i or the i th element of that component. Now, if you compare this one with this equation.

So, this is one equation for ϕ_i and here is an expression which we have written the generic expression.

(Refer Slide Time: 23:33)

Solution of linear systems

$$P_i = - \frac{b_i}{a_i + e_i P_{i-2} + (d_i + e_i a_{i-2}) Q_{i-1}}$$

$$Q_i = - \frac{c_i + (d_i + e_i a_{i-2}) P_{i-1}}{a_i + e_i P_{i-2} + (d_i + e_i a_{i-2}) Q_{i-1}}$$

$$R_i = \frac{f_i - e_i R_{i-2} - (d_i + e_i a_{i-2}) R_{i-1}}{a_i + e_i P_{i-2} + (d_i + e_i a_{i-2}) Q_{i-1}}$$

for $i=1 \& 2 \Rightarrow$

$$P_1 = -\frac{b_1}{a_1} \quad Q_1 = -\frac{c_1}{a_1} \quad R_1 = \frac{f_1}{a_1}$$

$$P_2 = -\frac{b_2}{a_2 + d_2 Q_1} \quad Q_2 = -\frac{c_2 + d_2 P_1}{a_2 + d_2 Q_1} \quad R_2 = \frac{f_2 - d_2 R_1}{a_2 + d_2 Q_1}$$

INDIAN INSTITUTE OF TECHNOLOGY KANPUR
Ashoke De 99

And, if you compare them together you get P_i is essentially nothing, but minus b_i by a_i plus $e_i P_{i-2}$ plus $d_i Q_{i-1}$. Similarly, one can write Q_i equals to minus it is c_i plus $d_i e_i Q_{i-2}$ plus P_{i-1} . And, in the denominator you have the same expression $e_i P_{i-2}$ plus d_i plus $e_i Q_{i-2}$ into Q_{i-1} . And, the last one is the R_i which is f_i minus $e_i R_{i-2}$ minus d_i plus $e_i Q_{i-2}$ into R_{i-1} . So, and the denominator is the same a_i plus e_i plus $d_i Q_{i-1}$.

Now, for i equals to 1 and 2 which can get you the specific expression like P_1 equals to minus b_1 by a_1 , Q_1 equals to minus c_1 by a_1 , R_1 equals to f_1 by a_1 . Same thing you can get P_2 equals to minus b_2 divided by a_2 plus $d_2 Q_1$ Q_2 equals to minus c_2 plus $d_2 P_1$ and R_2 equals to f_2 minus $d_2 R_1$ divided by a_2 plus $d_2 Q_1$. So, in this particular expression, if you put i equals to 1 or 2 you can get back this specific numbers.

(Refer Slide Time: 26:19)

Solution of linear systems

Since $b_{N-1} = b_N = c_N = 0 \Rightarrow P_{N-1} = P_N = Q_N = 0$

\hookrightarrow ϕ_{N-1} & ϕ_N can be found

$$\phi_N = R_N$$

$$\phi_{N-1} = Q_{N-1} Q_N + R_{N-1}$$

1. Compute: P_1, Q_1, R_1, P_2, Q_2 and R_2
2. For $i=3, 4, \dots, N$ use forward recursion to compute the values of P_i, Q_i & R_i
3. Compute: ϕ_N & ϕ_{N-1}
4. For $i=N-2, \dots, 3, 2, 1$ use backward recursion to compute the values of Q_i

INDIAN INSTITUTE OF TECHNOLOGY KANPUR Ashoke De 100

And, since you have $b_{N-1} = b_N = c_N = 0$ which will actually lead to $P_{N-1} = P_N = Q_N = 0$. So, from here one can find out ϕ_{N-1} and ϕ_N can be found using this information. And what could be that, once you get this two $\phi_N = R_N$ and $\phi_{N-1} = Q_{N-1} Q_N + R_{N-1}$. So, the specific one one can compute.

So, all these expressions if you put it back in the system then you can get the. So, the compute algorithm if somebody says you first compute P_1, Q_1, R_1, P_2, Q_2 and R_2 and then what you do for i goes from 3 4 to N use forward recursion to compute the values of P_i, Q_i and R_i . Then you compute ϕ_N and ϕ_{N-1} and then finally, for $i = N-2$ to 3 to 1 you use backward recursion to compute the values of Q_i . So, that is the essentially complete penta diagonal algorithm.

So, what you get first you obtained this specific one $P_1, Q_1, R_1, P_2, Q_2, R_2$ all these expression and then you go for the forward recursion. And, once you go for the forward recursion as we have obtained here all these P_i, Q_i, R_i you obtain. And, once you obtain all these you go and calculate the ϕ_N and ϕ_{N-1} using this and then finally, you go for the backward recursion to compute the value of Q_i . So, this is this completes the algorithm for the penta diagonal. So, these are the discussion on direct approach. Now, in the next lecture we carry on the iterative process.

Thank you.
