Lecture - 34
Kinetics of Substrate Utilization, Product formation and Biomass Production of
Microbial Cells – IV

Welcome back to my lecture that Aspects of Biochemical Engineering. Now, last couple of lecture, I try to concentrate on cell growth kinetics that we discussed the cell growth kinetics both for the batch system and the continuous system. And when we discuss the chemostat process, I told you that, we know the continuous stirred tank reactor. When continuous stirred tank reactor we use in the biological system, this is we call it chemostat.

And major drawback of the chemostat process is the cell mass that is going out of the system. Now, if the rate of cell mass that is going out of the reactor, is more as compared to rate of a cell mass that is growing in the system, then what will happen is, situation will come when there will be no cell present in the reactor. Now that situation, we can overcome by using 2 different approaches.

One is called cell mass recycling, that another we called immobilized whole cell. Now, there, so today, I shall concentrate on that you know how with the help of cell mass recycling, we can control the cell mass waste in your wasting in your from the system or the wash out of the cells.

(Refer Slide Time: 01:55)

Chemostat with cell mass recycle

- ✓ Chemostat recycle is performed to keep the cell concentration higher than the normal steady-state level in a chemostat
- ✓ Cell recycle increases the rate of conversion (or productivity)
- ✓ Increases critical dilution rate for washout thereby increases operating flexibility
- ✓ Can be performed using a centrifuge or settling tank to concentrate biomass leaving the reactor.

Handwritten diagram and notes: A rectangular reactor with an inlet flow F and an outlet flow F_2 . A side stream is labeled "Cell wash out". To the right, a circular symbol contains $(F_2) \left(\frac{dx}{dt} \right)$. Further right, the equation $\frac{1}{D} = \#RT$ is written.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | DEBABRATA DAS, DEPARTMENT OF BIOTECHNOLOGY, IIT KHARAGPUR

Now, first, you know, let me explain this, because, suppose this is C S T R, and this will continuously liquid is coming at a particular flow rate and going out at the particular flow rate.

Now, here x_0 this is x and this is also x . Now what I want to point out that, always you will be having cell wastage, what is called F into x , am I right? So, if this is equal to rate of growth of the cells inside the cell, inside the reactor, then it is fine. Because, if it is the growth, say that, you know that if the rate of growth is same as that, then it is fine. Otherwise, if it is more than that, then the cell concentration will decrease with respect to time. A time will come when there is no cell present in the reactor.

Now, another explanation to this process I explained that is the generation time; because, 1 by D is considered as the hydraulic retention time. Now, what is hydraulic retention time means, how long you allow a particular liquid research in the reactor. Now if you have generation time is more than that hydraulic retention time, then what will happen that your liquid will get less time. So, naturally your cells will not grow inside the reactor and before it grows, you are taking out the liquid from the reactor. That is why, we phase the situation what we call cell wash out.

Wash out means, the after some time, you will find there is no cell present inside the reactor. This is the major drawback of the chemostat process.

(Refer Slide Time: 03:49)

Chemostat with cell mass recycle

- ✓ Chemostat recycle is performed to **keep the cell concentration higher than the normal steady-state level in a chemostat**
- ✓ Cell recycle **increases the rate of conversion (or productivity)**
- ✓ **Increases critical dilution rate for washout** thereby increases **operating flexibility**
- ✓ Can be performed using a centrifuge or **settling tank to concentrate biomass** leaving the reactor.

The slide features a hand-drawn red diagram of a chemostat system with a recycling loop. The diagram shows a reactor on the left, a separator on the right, and a return line from the separator back to the reactor. Arrows indicate the flow of liquid and cells. A circled '2' is drawn on the return line.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | DEBABRATA DAS, DEPARTMENT OF BIOTECHNOLOGY, IIT KHARAGPUR

Now, this can be overcome. How you can overcome? This can be overcome, suppose, the whatever x_s cell mass is going, so, if you put a separator here and we can and part of the cell, you are recycling back to the system to maintain the cell mass concentration uniform, then and all then your rate of reaction will be constant. Then there will not be any problem of cell washout. So, this we will discuss here.

The chemostat, we sell must recycling the chemostat recycling is performed to keep the cell higher than the normal steady state level in make chemostat. So, we recycle in the manner, so that, you cell mass concentration it remain constant higher than that. So, we ensured that, your rate of reaction is constant or more than that, we have we desire that is, cell recycling increases with the rate of conversion. And obviously, that increases in a critical dilution rate for wash out there, but increases the operating flexibility.

And can be performed using the centrifuge or settling tank or to concentrate biomass leaving the reactor.

(Refer Slide Time: 05:11)

So, if we see that you know that C S T R of the cell mass recycling system, it basically looks like this. So, this is rotation; this is like this. So, here we can have the settler and this is going out and part of the things you recycle back and part use. So, here what you call cell recycling, this is recycling. And this is called cell wasting.

And, this is actually the effluent; there is a clear liquid effluent. This is the feed we have. Now, suppose, this is the settle cell mass concentration x_u and this is x_f . When you settle, obviously, the cell mass concentration will be more here; and this is the settle cell mass concentration. And let us assume, the recycle flow rate is F_R and this is the F_0 . Then, what will be here, flow rate? F_0 plus F_R , am I right? So, what is the cell that is going out going in? If we assume this is x_0 , so, we can write F_0 into x_0 plus this is recycling; this is also x_u .

This is plus F_R into x_u this is equal to what if a x then, plus there will be some production generation. This is plus the rate of growth of the cells inside the system this is into v this will be equal to $F_R F_0$ plus F_R into x_0 x we can write like this. So, this is the main purpose of recycling we want to maintain this cell mass concentration uniform or above certain concentration what we really looking for.

(Refer Slide Time: 07:17)

Chemostat with cell mass recycle

The figure shows schematic of a chemostat operated in recycle mode where:

F_0 : Input Feed flow rate
 S_0 : Initial substrate concentration
 X_0 : Initial cell mass concentration
 F_2 : Output Feed flow rate
 S : Output substrate concentration
 X : Steady state cell mass concentration
 F_R : Recycle Feed flow rate
 X_U : Recycle cell mass concentration
 F_e : Effluent Feed flow rate
 X_w : Effluent cell mass concentration

DEBABRATA DAS
 DEPARTMENT OF BIOTECHNOLOGY
 IIT KHARAGPUR

Now, this is the process how you can be explained in pictorially like this. So, here, as I told you, this is the process, this is the CSTR we have continuous starting reactor or chemostat. And this is the influent and this is what is going out and this is the separator; cell separator concentrated of the cells is there a part you recycle back. This is the recycle flow rate, this is the settlement this is waste recycle flow rate. Yes, we assume here when we carry out the reaction only take place in the reactor; reaction does not take place in the separator of the pipeline. Then we can write the balance equation.

So, here all the parameters are noted here that you know how these are different F_0 , S_0 and X_0 and all the parameter what they are stands for.

(Refer Slide Time: 08:26)

Chemostat with cell mass recycle

At steady state, the cell mass balance across the chemostat can be given as:

Input + Generation = Output + Accumulation + Cell death
 $(F_0 X_0 + F_R X_u) + V \cdot \frac{dX}{dt} = F_a X + 0 + 0 \dots (1)$

Now, it should be noted that $\alpha = \frac{F_R}{F_0}$, where α is the recycle ratio

So, $F_R = \alpha F_0 \dots (2)$

Also, $F_a = F_0 + F_R$

Therefore, $F_a = F_0 + \alpha F_0 \rightarrow F_a = F_0 (1 + \alpha) \dots (3)$

From Eq. (2) and (3), Eq. (1) can be written as:
 $(F_0 X_0 + \alpha F_0 X_u) + V \cdot \frac{dX}{dt} = F_0 (1 + \alpha) X + 0 + 0 \dots (4)$

$F_a = F_0 + F_R$
 $= F_0 + \alpha F_0$
 $= F_0 (1 + \alpha)$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | DEBABRATA DEPARTMENT OF B IIT KHARAGPUR

Now, here, question comes, how you can write the balance equation? Let us first consider the cell mass balance across the chemostat. How we can write? I told you what is the input equal to F_0 into X_0 F_1 into X_0 this is the F_1 into X_0 and this is the input to the cell and what is the generation that we have? This is the generation V into X by Dt . And what is the output? This is the output, am I right? F_a is what F_a is equal to F_0 plus F_R . So, this is into X and plus accumulation under steady state condition.

So, if we, since we mentioned the steady state condition, we can assume the rate of accumulation is the 0 and also, we can assume that there is no cell death take place. Then what we can write that α equal to F_R by F_0 and α is considered as the recycle ratio. So, what is the F_R is equal to what? α into F_0 .

Now, F_a equal to F_0 plus F_R , am I right? Then, F_0 plus α into F_0 , F_R equal to. So, I can call a common F_0 . I can write $1 + \alpha$. This is exactly what is written here. Now, this equation can be modified in this form that, this is a same serve we have the F_0 into X_0 F_R is equal to α into F_0 into X_u and this is like this F_0 this we can modify at F_0 into $1 + \alpha$ into X .

(Refer Slide Time: 10:20)

Chemostat with cell mass recycle

For sterile feed $X_0 = 0$; So Eq. (4) becomes

$$\alpha F_0 X_u + V \cdot \mu X = F_0 (1 + \alpha) \cdot X \quad (\text{since } \frac{dX}{dt} = \mu X)$$

Dividing above equation by V, we get

$$\alpha \frac{F_0}{V} X_u + \mu X = \frac{F_0}{V} (1 + \alpha) \cdot X$$

$$\alpha D X_u + \mu X = D (1 + \alpha) \cdot X \quad (\text{Since } \frac{F_0}{V} = D) \quad \dots (5)$$

Now, $C = \frac{X_u}{X}$ where C is the concentration ratio.

So, $X_u = CX$; putting in Eq. (5) we get

$$\alpha DCX + \mu X = D (1 + \alpha) \cdot X$$

By rearranging we get;

$$\mu = D [1 + \alpha(1 - C)] \quad \dots (6)$$

Handwritten red notes on the slide:
 $C = \frac{X_u}{X}$
 $X_u \gg X$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | DEBABRATA DEPARTMENT OF BIOTECHNOLOGY IIT KHARAGPUR

Then what we can write that, we can write in a b b s equation was like this.

And then we can write this is alpha into F 0 this is what we have alpha into F 0 and b into F 0 and because we considered x 0 equal to 0. So, first time we can add that you can neglect and that is equal to this. And this equation, I can write now, we can divide by V both sides and if you divide by F 0 by V equal to what dilution rate. So, this we can modified in this form. Now that now we can assume, C equal to X u by C if you write C equal to X u by X. Now, x x u what settle cell mass concentration.

And X is the cell mass concentration under in the reactor under sterile. So, X u is usually much higher than X. So, I can always say, that C is sorry.

(Refer Slide Time: 11:32)

Chemostat with cell mass recycle

For sterile feed $X_0=0$; So Eq. (4) becomes

$$\alpha F_0 X_u + V \cdot \mu X = F_0 (1 + \alpha) \cdot X \quad (\text{since } \frac{dX}{dt} = \mu X)$$

Dividing above equation by V, we get

$$\alpha \frac{F_0}{V} X_u + \mu X = \frac{F_0}{V} (1 + \alpha) \cdot X$$

$$\alpha D X_u + \mu X = D (1 + \alpha) \cdot X \quad (\text{Since } \frac{F_0}{V} = D) \quad \dots (5)$$

Now, $C = \frac{X_u}{X}$ where C is the **concentration ratio**.

So, $X_u = CX$; putting in Eq. (5) we get

$$\alpha D C X + \mu X = D (1 + \alpha) \cdot X$$

By rearranging we get;

$$\mu = D [1 + \alpha(1 - C)] \quad \dots (6)$$

Handwritten red annotation: C >> 1

I can write C always much greater than 1. So, this is like the c equal to the concentration ratio of that. Now we can write X u equal to C into X. Now this we can write in this form then, the X u value how we can put C into X? So, this equation can be modified as like this. Now, what is the significance of this equation? Let us try to find out now here that.

I can write mu by D is equal to 1 plus alpha 1 minus C.

(Refer Slide Time: 12:03)

Chemostat with cell mass recycle

For sterile feed $X_0=0$; So Eq. (4) becomes

$$\alpha F_0 X_u + V \cdot \mu X = F_0 (1 + \alpha) \cdot X \quad (\text{since } \frac{dX}{dt} = \mu X)$$

Dividing above equation by V, we get

$$\alpha \frac{F_0}{V} X_u + \mu X = \frac{F_0}{V} (1 + \alpha) \cdot X$$

$$\alpha D X_u + \mu X = D (1 + \alpha) \cdot X \quad (\text{Since } \frac{F_0}{V} = D) \quad \dots (5)$$

Now, $C = \frac{X_u}{X}$ where C is the **concentration ratio**.

So, $X_u = CX$; putting in Eq. (5) we get

$$\alpha D C X + \mu X = D (1 + \alpha) \cdot X$$

By rearranging we get;

$$\mu = D [1 + \alpha(1 - C)] \quad \dots (6)$$

Handwritten red annotations:
 $\alpha = \frac{F_R}{F_0}$
 $\frac{\mu}{D} = 1 + \alpha(1 - C)$
 $= 1 + 0.5(1 - 2.5)$
 $= 1 + 0.5 \cdot -1.5$
 $= 1 - 0.75$
 $= 0.25$

Now what is 1? What is alpha? Alpha is the recycle ratio, alpha equal to what F R F R recycle flow rate by F 0 and this usually less than 1 because, usually the recycle ratio

always will be less than 1. So, let us assume it is of 50 percent 0.5. Let us assume that. And 1 minus and I told you C always should be greater than 1. So, if we assume, this is 2 or you know 2.5 still is assume that then what will happen.

That 1 plus 0.5 into this will be 1 minus 1.5. 1.5 is how much this will be after 1 minus 0.75. So, this will be 0.25. Now, if it is 0.25, so what I can write? The mu by D equal to 0.25.

(Refer Slide Time: 13:10)

Chemostat with cell mass recycle

For sterile feed $X_0 = 0$; So Eq. (4) becomes

$$\alpha F_0 X_u + V \cdot \mu X = F_0 (1 + \alpha) \cdot X \quad (\text{since } \frac{dX}{dt} = \mu X)$$

Dividing above equation by V, we get

$$\alpha \frac{F_0}{V} X_u + \mu X = \frac{F_0}{V} (1 + \alpha) \cdot X$$

$$\alpha D X_u + \mu X = D (1 + \alpha) \cdot X \quad (\text{Since } \frac{F_0}{V} = D) \quad \dots (5)$$

Now, $C = \frac{X_u}{X}$ where C is the **concentration ratio**.

So, $X_u = CX$; putting in Eq. (5) we get

$$\alpha DCX + \mu X = D (1 + \alpha) \cdot X$$

By rearranging we get;

$$\mu = D [1 + \alpha(1 - C)] \quad \dots (6)$$

Handwritten notes:
 $\frac{\mu}{D} = 0.25$
 $\frac{D}{\mu} = \frac{1}{0.25} = 4$
 $\mu = D$
 ~~$D = 4\mu$~~

So, that means, that in a C S T R, under steady state condition and still mu equal to D. And, but here, is mu equal to 0.5; that means, you can if D by mu is there, how much that is 1 by 2.5; that means, this is 4.

That means that, you know I can write mu equal to or I can write D equal to 4 mu. So, I can run this if you do the recycling, I can write 4 times of this; that is, the specific growth of the cells. So, this is the speciality of the recycling of the cells.

(Refer Slide Time: 14:14)

Chemostat with cell mass recycle

For sterile feed $X_0 = 0$; So Eq. (4) becomes

$$\alpha F_0 X_u + V \cdot \mu X = F_0 (1 + \alpha) \cdot X \quad (\text{since } \frac{dX}{dt} = \mu X)$$

Dividing above equation by V , we get

$$\alpha \frac{F_0}{V} X_u + \mu X = \frac{F_0}{V} (1 + \alpha) \cdot X$$

$$\alpha D X_u + \mu X = D (1 + \alpha) \cdot X \quad (\text{Since } \frac{F_0}{V} = D) \quad \dots (5)$$

Now, $C = \frac{X_u}{X}$ where C is the concentration ratio.

So, $X_u = CX$; putting in Eq. (5) we get

$$\alpha DCX + \mu X = D (1 + \alpha) \cdot X$$

By rearranging we get;

$$\mu = D [1 + \alpha(1 - C)] \quad \dots (6)$$

If you recycling of the cells, how you can justify, that we can operate the same system safely now, we have already seen that, when you plot that you know $\alpha D X_u$ versus D , that of what we have done, we have plot like this, am I right? And this is the situation that we have here, this is called D washout.

And at the same time, we find that, here this is what, this is called D max. Now, suppose, in case of bakers, yeast fermentation process, we wanted to have maximum amount of cell mass formation. So, what is the maximum cell productivity? Maximum cell productivity is how much productivity equal to D max into x , where the D max what is the x value that is the maximum. Now, as I told you, that D max and D washout, these 2 they are very close to each other. So, if you increase a little bit the flow rate, because D equal to what F by V .

Now, if you increase the flow rate little bit high, there is every possibility that D (Refer Time: 15:18) max can meet the D washout situation, then we will not get any cell mass in the reactor. Now this system can be safely operated if you recycle the cell. So, even it is the increase little bit, it is not going to effect in your system at all. So, this is how we can safeguard the cell wash out by the cycling of the cells.

(Refer Slide Time: 15:39)

Chemostat with cell mass recycle

At steady state, the substrate mass balance across the chemostat can be given as:

0

Input + Generation = Output + Consumption + Accumulation

$$(F_0 S_0 + F_R S) + 0 = F_a S + V \frac{dS}{dt} + 0 \dots (7)$$

From Eq. (2) and (3), Eq. (1) can be written as:

$$F_0 S_0 + \alpha F_0 S = F_0 (1 + \alpha) S + V \left(\frac{dS}{dt} \right)$$

$$F_0 S_0 + \alpha F_0 S - F_0 S - \alpha F_0 S = V \left(\frac{dS}{dt} \right) \quad \left(\text{Since } \frac{dX}{dS} = Y_{X/S}; \frac{dX}{dt} = \mu X \right)$$

$$F_0 (S_0 - S) = V \left(\frac{1}{Y_{X/S}} \mu X \right)$$

$$D(S_0 - S) = \frac{1}{Y_{X/S}} \mu X \quad \left(\text{Since } D = \frac{F_0}{V} \right)$$

$$X = \frac{D(S_0 - S)}{\mu} Y_{X/S}$$

Then we try to find out that, steady state substrate mass balance across the chemostat. We can write $F_0 S_0 + F_R S = F_a S + V \frac{dS}{dt} + 0$. This is $F_0 S_0 + F_R S$ because, we assume here this will be S , so, $F_R S$ here also it will be S .

Here of the everywhere it will be S and this is equal to F into and no generation of the cells that will be substrate. This will be 0 this is $F_a S$ plus that you know rate of substrate that is degraded consumption in the system and rate of accumulation that should be equal to 0 .

Now, if you do the analysis of the process like this we will come across these equation $D(S_0 - S) = \frac{1}{Y_{X/S}} \mu X$. So, X will be equal to what $D(S_0 - S) Y_{X/S}$ by S this is cell mass concentration and we can easily determine like this.

(Refer Slide Time: 16:48)

Chemostat with cell mass recycle

Putting value of μ From Eq. (6), we get

$$X = \frac{(S_0 - S)}{1 + \alpha(1 - C)} \cdot Y_{X/S} \quad \dots (8)$$

Thus, the biomass increases by a factor of $\frac{1}{1 + \alpha(1 - C)}$ as compared to chemostat without recycle.

The substrate concentration 'S' can be obtained by applying Monod kinetics to Eq. (6)

$$\frac{\mu_{max} S}{K_S + S} = D [1 + \alpha(1 - C)]$$

By rearranging,

$$S = \frac{K_S D [1 + \alpha(1 - C)]}{\mu_{max} - D [1 + \alpha(1 - C)]} \quad \dots (9)$$

Putting S value in Eq. 8, we get:

$$X = \frac{Y_{X/S}}{[1 + \alpha(1 - C)]} \left[S_0 - \frac{K_S [1 + \alpha(1 - C)] D}{\mu_{max} - [1 + \alpha(1 - C)] D} \right]$$

Handwritten note: $z = Y_{X/S}(S_0 - S)$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | DEBABRAJ DEPARTMENT OF B IIT KHARAGPUR

Now, μ that X equal to this we can see that we wrote like this and before that, we have derived this equation $\mu = D(1 - \alpha(1 - C))$. So, this I can put it here and final equation will be this. And then does the biomass increase by a factor of this as compared to the chemostat without recycling. So, this is the comparison that we have made and then substrate concentration can be obtained by applying Monod kinetics like this equation that we have.

And this already, we find this is equal to μ and Monod question is this and then we find out the S value. S value will be this and Y value that the X value will be what $Y_{X/S}(S_0 - S)$. So, if you put the S value here, then you can calculate the value of X, but both S and X value you can calculate with this, with the recycling system.

(Refer Slide Time: 18:09)

Now, if you plot this dilution rate with the biomass concentration and what will observe what we will get and the rate of biomass formation both say, if you get here, then you will find that, this is the X, this is the true situation.

We have R_1 and R_2 . What is the R_1 ? R_1 is the cell mass output for volume without recycling and R_2 is with recycling. So, with recycling, you would the cell mass with concentration will be like this and you can see that you are D washout. D washout is much higher as compared to without recycling. Without recycling, it may be close to 1 and it is about 2 and R also R_1 that is the cell mass output for without is that has been given here.

This is the 2 situation that we have rate of cell mass formation. In case of without recycling rate of cell mass formation, in case of with recycling this with recycling, our cell mass growth is increased to a great extent.

(Refer Slide Time: 19:38)

Continuous operation using Plug-Flow Reactor

- ✓ Analysis of plug flow reactor for cell culture follows same procedure as for enzymatic reaction.
- ✓ **Material balance** for cell mass in small section (ΔZ) can be given as

Input + generation = Output + Consumption + Accumulation

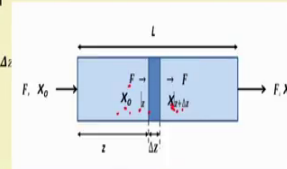

$$FX_{0z} + \mu X \cdot A \Delta z = FX_{z+\Delta z}$$

$$F(X_{z+\Delta z} - X_{0z}) = \mu X \cdot A \Delta z$$

$$\frac{X_{z+\Delta z} - X_{0z}}{\Delta z} = \mu X \quad (u = \frac{F}{A}, \text{Superficial velocity})$$

Applying limit $\Delta z \rightarrow 0$ to above equation we get

$$u \left(\lim_{\Delta z \rightarrow 0} \frac{X_{z+\Delta z} - X_{0z}}{\Delta z} \right) = \mu X \quad \text{or} \quad u \left(\frac{dX}{dz} \right) = \mu X$$

A - Cross-sectional area of the reaction

F - Volumetric flow rate

$dV = A \Delta z$

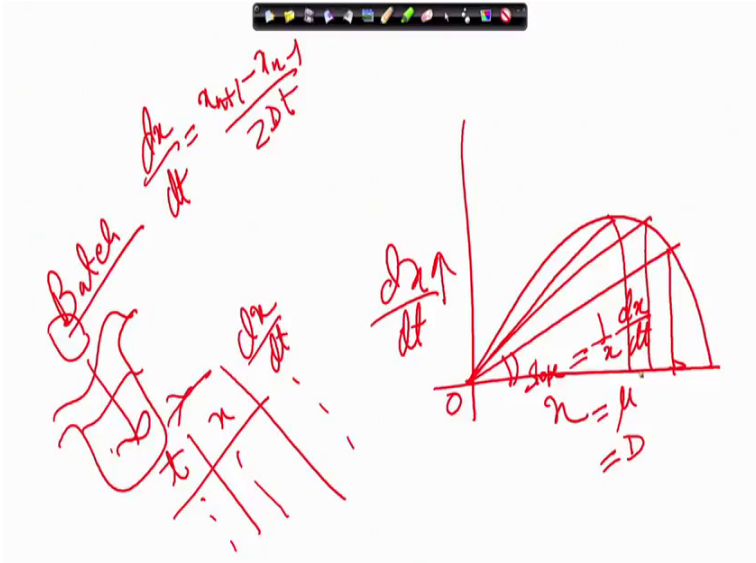

DEBABRATA
DEPARTMENT OF BIOTECHNOLOGY
IIT KHARAGPUR

Now, that you know after here, I want to point out one thing; that one thing I point out that you know.

(Refer Slide Time: 19:52)

Batch $\frac{dX}{dt} = \frac{n+1 - X}{2 dt}$

slope = $\frac{dX}{dt}$
 $n = \mu = D$

We have seen the batch process; batch process that is like this.

So, we take the material at a time, allow it to react. After the reaction is over, you take it out. Now, here, with respect to time, you can have the cell mass concentration. So, then we can monitor dX by dt . Though how we can monitor dX by dt ? I told you dX by dt equal to $X^{n+1} - X^{n-1}$ divided by $2 \Delta t$. Now if it is like this. Now, if

you plot $X \frac{dX}{dt}$, mass is X what kind of nature of plot we will get like this. Now, what is the slope? This slope this is 0. So, slope is the $\tan \theta$. $\tan \theta$ is the altitude by base.

So, it is $\frac{dX}{dt} \frac{1}{X}$ this is equal to slope this in the angle these like this. So, this is nothing but equal to μ and this μ under steady state condition and sterile field in case of V the chemostat this is equal to D . So, the best data that can be possible from the best data it is possible to find out that, what will be the cell mass concentration in a chemostat at a particular dilution rate provided you have the plot of dX versus X . Now if you have this dilution rate, then you can find out the corresponding the cell mass concentration.

Now, if you have this one is dilution rate, you can find the corresponding. So, without going for this operation of the content process, it is possible by simple operation of the batch processes possible to find out what should be the cell mass concentration in a chemostat. Now, let me explain that, how we can analyse the plug flow reactor. It is similar to the plug flow reactor. When we discuss during the in geometric reaction, the analysis of the plug flow reactor plug culture follows the same procedure as the enzymatic reaction. The material balance in this section is like this.

So, I told you this is kind of tubular flow and plug flow is kind of tubular flow. So now, here this equation is like this, that F the F is the flow rate and X is the z here X_0 into z . So, this is z and this is the X_z plus X .

So, this is the input and then rate of growth of the cells this is the generation of the cells and then output. And we can assume the consumption. And this, we under steady state condition, this is equal to 0. Then we can write this equation in this form; this is F into X_z plus the Δz and the X_0 into z and this equal to this is the F divided by A . A is the cross-sectional area. If you divide by this, you will get the velocity. Velocity is that into this equal to u . Now, if z equal to tends to 0, then what we can write, this is equal to we can write that $\frac{dX}{dz} \frac{1}{u} = D$ that $\frac{dX}{dz} = \mu X$.

(Refer Slide Time: 23:44)

Continuous operation using Plug-Flow Reactor

Rearranging and integrating above equation we get

$$u \int_{X_0}^X \frac{dX}{X} = \mu \int_0^L dz$$

$$\ln \frac{X}{X_0} = \mu \frac{L}{u}$$

$$\text{So, } \ln \frac{X}{X_0} = \mu \frac{V/A}{F/A} = \ln \frac{X}{X_0} = \mu \tau$$

Therefore, $\tau = \frac{1}{\mu} \ln \frac{X}{X_0}$

The above equation suggests that $\tau_{PFR} = \tau_{Batch}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | DEBABRATA DEPARTMENT OF B IIT KHARAGPUR

Now, if you do the integration that, you know that u is the velocity and dX by $X u$ will be dz . And so, this is the reactor that we have a strip here. So, this is dz . This is the length is dz .

Now, we integrate it from 0 to 0 to L this is the L . So, if you integrate that, then we will find L by u , you can bring it here and this is X . X_0 they will started with X_0 and finished with X ; that is, the cell mass concentration. Then, we can have this is the L by u , then this is this equation and then and L is what L by u . The L what is the unit is it length. And what is the unit of u length per unit time? So, you know length will cancel the time will come.

So, L by u is nothing but τ . So, this we can replace the $\ln X$ by X_0 equal to τ . So, we can write the τ that is, the space time of the plug flow reactor is L by $\mu \ln X$ by X_0 . So, this is the same as the expression. If you compare with the batch process, the τ plug flow reactor is equal to τ , the batch process the same expression that we have.

Drawbacks of Plug-Flow Reactor

- ✓ Not suitable for the growth of suspended cells
- ✓ Can be used using recycle or immobilized cell reactions however the inherent operational problems cannot be avoided
- ✓ Difficult to control due to temperature and composition variations
- ✓ PFR maintenance is also more expensive
- ✓ Rarely employed in Industrial fermentations

The slide includes two hand-drawn diagrams in red ink. The top diagram shows a rectangular reactor with an arrow pointing into the left side and an arrow pointing out of the right side. The bottom diagram shows a cylindrical reactor with an arrow pointing into the bottom and an arrow pointing out of the top. The slide footer contains the IIT Kharagpur logo, NPTEL Online Certification Courses logo, and the name DEBABRATA DEPARTMENT OF B IIT KHARAGPUR.

The drawbacks of the of the block flow reactor, it is not suitable for the growth in suspension because, I told you that in the plug flow reactor, there is no back mixing.

So, if there is a suspended cell, there is every possibility it will settle down. Then, it is not suitable and can be used recycle or immobilized cell reactions. So, suppose, in a column, if you pack the cells in a immobilized column and you pass the substrate here, take out, that is you know, that kind of system we can operate it in the plug flow manner. However, the inherent operational problem cannot be avoided. Because, inherent proper what is the operation problem, there should not be any and that you know back mixing the difficult to control the temperature and composition variation.

Because, if you suppose, in this reactor, if you make a concentration profile with respect to distance that $S \propto 0$, then what will be with respect to distance at different distance, your substrate concentration will be different. So, difficult to control the temperature reason is that, there is no hesitation to master it. Heat transfer will not be proper and composition variations of I showed you, how the composition variations is there. Plug flow maintenance is also more expensive and rarely employed for the industrial purposes. So, this is what we have that plug flow reactor is rarely used.

Comparison between major modes of cultivation

- ✓ Kinetic characteristics of PFRs are same as the Batch reactors
- ✓ When large number of CSTRs are connected in series, the conversion characteristics approach those of Batch and PFRs
- ✓ Rates of conversion in chemostat operated at D_{max} are 10-20 times greater than PFR or Batch.
- ✓ For most fermentations, CSTRs offer significant theoretical advantages over other modes of reactor operation.
- ✓ However, despite the benefits of CSTR, the majority of commercial fermentations are conducted in Batch
- ✓ Batch fermentations have lower risk of contamination as compared to CSTR
- ✓ Equipment and control failures during long term operation are the associated problems with CSTR

Bioprocess Engineering Principles by Pauline M. Doran

Now, comparison between the major mode of cultivation, what I lastly pointed out the kinetic characteristics of plug flow reactor is same as batch process. Large number of C S T R connected in series conversion characteristics approaches to. So, those of plug flow reactor I showed you that, when you plot to minus r_A versus C_A in the chemical reaction, I showed you if you have this in case of product change, you know, this is in case of product inhibition. We go for this is tau plug flow reactor. Now, this is can be, but in case of C S T R, it will be area is node.

But, this can be replaced by a multiple C S T R like this. So, you have multiple C S T R, this can be number noise number of C S T R connected in series the conversion characteristic approaches in the batch and plug flow reactor. The rate of conversion of chemostat operation D_{max} in 10 to 20 times greater than plug flow reactor. And batch process for the most fermentation, the C S T R offers significant theoretical advantage over the other nodes of reactor operation with they can be very easily operated as simple stirred tank reactor.

You pass your substrate one end and take out product other end; however, despite the benefit of C S T R, majority of the commercial fermentation is conducted in the batch mode because, they always continuous process required some kind of skill of operation. And batch fermentation is lowered risk of contamination as compared to C S T R. This we already pointed out the C S T R.

When you operate for long time, there will be some kind of contamination problem and whereas, in case of batch system, the contamination problem comparatively very less equipment and control failure during the long-term operation are associated with the problem of with the C S T R. So, and this is basically, the instrumental controls. So, if they need any kind of instrumentation failure is there, then the process is going to suffer. So, these are the several problems we face during the operation of C S T R.

So, what I try to point out here that, the major problem that we have with the chemostat process is, the cell mass wasting from the reactor and that can be and meeting the situation like cell washout. And since, that problem can be easily overcome if we recycle the cell in their solid matrix and is recycle the cell in the particular reactor and later on we find that, how we can determine the space time that is required in the plug flow reactor. And finally, we make a clear cut the difference between chemostat at the plug

flow reactor the batch process and what I pointed out that batch process contamination problem will be less. But, you know productivity would be more in the case of C S T R and plug flow reactor will be very difficult to operate.

Thank you very much.
