Lecture – 11
Fundamentals of Optical Measurement and Instrumentation

Hello and welcome to the lecture series on optical spectroscopy and microscopy. So far in this lecture series, what we have seen is that how to describe the interaction of the light with the matter with the idea that if we can actually quantitatively develop a framework of understanding the way or describing how the light interacts with the matter and that might probably provide us with a fundamental understanding of how this whole process happens and then it might help us in understanding the complex processes or other processes that might happen as a consequence of this basic interaction.

In that direction, what we have done is we have looked into the time-dependent perturbation theory and in our formalism, how we use the Dirac's quantum mechanics formalism of eigenkets and bras and we use those properties to obtain an expression for the expansion coefficients a_k , to be more precise we were actually writing down an expression for \dot{a}_k in the last lecture, alright. So now show you how we can proceed forward and get an expression for \dot{a}_k itself and what it means and how does it relate to the practical situation okay.

(Refer Slide Time: 02:17)

The image shows a whiteboard with handwritten mathematical equations. At the top, the expansion of a state vector is given as $\sum_n a_n \langle e_k | H | e_n \rangle e^{-iE_n t / \hbar} = e^{-iE_k t / \hbar} [\dot{a}_k(t) - \frac{a_k(t) i E_k t}{\hbar}]$. A checkmark is next to the first part. Below this, the differential equation for $\dot{a}_k(t)$ is derived: $\dot{a}_k(t) = -\frac{i}{\hbar} \sum_n a_n \langle e_k | H | e_n \rangle \cdot e^{-\frac{i E_n t}{\hbar}} \cdot e^{i E_k t / \hbar}$, which simplifies to $= -i \sum_n a_n \langle e_k | H | e_n \rangle \cdot e^{-i \Delta E_n t / \hbar}$ where $\Delta E_n = E_n - E_k$. The final equation is boxed: $\dot{a}_k(t) = \sum_n a_n \langle e_k | H | e_n \rangle \cdot e^{-i \Delta E_n t / \hbar}$. There are some additional annotations like a circled '5' and arrows.

So now the equation that we had in the last lecture was this, $\dot{a}_k(t) = \sum_n a_n \langle e_k | H | e_n \rangle e^{-i \Delta E_n t / \hbar}$. So that is the expression that

we had. So until now, we have not made any approximations. We have made some assertions, we made some assumptions, but we never made any approximations until here. So if you could evaluate these terms and write down these terms, then the solution that we get for the derivative of a_k is very exact.

So you could get this solution and integrate it, integrate it over time 0 to t , then get an expression for a_k itself and that would be a true description or exact description of the system as a function of time after you let the system interact with the light. Now while it can be very exact and wonderful to write down this expression, practically it may not be of that greater use if you do not make a few further progress to relate it to an experimentally observed quantities, right.

So in order to do that, we have to make some approximations from now on because it is little too cumbersome to deal with this expression as such **so** and it is convenient to make that approximation, it makes more sense as you see in real life that those kind of approximations really hold good. So what are those approximations?

(Refer Slide Time: 04:17)

Handwritten mathematical derivation:

$$H = H_0 + \lambda H(t)$$

↳ "turning on" parameter

$$a_n(t) = f(H, \lambda)$$

$$= \sum_j a_n^{(j)} \lambda^j = (a_n^{(0)} \lambda^0 + a_n^{(1)} \lambda^1 + \dots + a_n^{(j)} \lambda^j)$$

$$\dot{a}_k(t) = \frac{d}{dt} \left[\sum_j a_k^{(j)} \lambda^j \right] = \sum_n (a_n^{(0)} \lambda^0 + a_n^{(1)} \lambda^1 + \dots) \langle e_k | \lambda H | e_n \rangle e^{-i\Delta E_n t / \hbar}$$

$$(\dot{a}_k^{(0)} \lambda^0 + \dot{a}_k^{(1)} \lambda^1 + \dots) = \sum_n (a_n^{(0)} \lambda^0 + a_n^{(1)} \lambda^1 + \dots) \langle e_k | H | e_n \rangle e^{-i\Delta E_n t / \hbar}$$

Number one we realize the Hamiltonian that we have written right, the time-dependent perturbation Hamiltonian we have wrote it as the sum of the unperturbed Hamiltonian plus the perturbation itself. Now here, I am going to introduce a small change here that is I am going to say it is not just H but at term λH okay, where H is the perturbation and it is of course a function of t . So when you do this, the λ is called as typically turning on parameter.

Simply what it means is that as the value of λ changes from 0 to 1, it equates it to you letting the system interact with the light, I mean, or with any perturbation for that matter, right. So when $\lambda = 0$, there is no perturbation because this whole term goes to 0 and when λ becomes equal to 1, the perturbation is fully on right. In some ways, its like a switch that you flip to turn the perturbation, if you like. It is not exact but I am just going to kind of a little bit of a stretch here.

What you can think of is that λ in turn is also a function of time, but you know in a very specific way. The way being that it is 0 until a point $t = t_0$ okay, I mean some $t = t_0$ okay. This is the time axis until $t = t_0$, it is actually 0 alright. At $t = t_0$, you are turning on this λ from that point onwards right at $t = t_0$, from that point onwards you have a value of some amplitude A which is greater than 0, so I was going to write it as 1, but you can think of that as some amplitude A to be general.

See that the problem, I am just going to tell you the problem of just generally writing λ as a function of t is that you will later realize that the whole point of me trying to do this λ business is to be able to expand my coefficients a_n , right. I know this a_n is a function of t and of course it is changing as a function of t only because of this perturbation being applied right, otherwise these a_n are corresponding to the expansion coefficients of the basis eigenkets which are basically eigenkets of the H_0 itself.

So, it depends on which of a_n that are occurring that will be there. So, it is just like once and 0, whether the system is in a state a_n or not, so that settle right that it does not change with respect to time. These a_n then represent the initial states of the system per se. So in that case, this a_n definitely are a function of the perturbation Hamiltonian H . Now if I say I am going to write it as λ times H , I actually would like to write it as H and as a function of λ .

Once I say this, then what it allows me to do is that I would be able to write it as I mean if I write it as this, it is clearly as a function of H and in fact I can write it as a function of H and λ , so I can then do a power series expansion for a_n in terms of λ . Now if I were to do that, then it would be something similar to a_n . So if I am going to write it as a power series

expansion, I will write it as for j terms, I mean j going from 0 to infinity and of j , j in the parentheses here represents the coefficient, the j th coefficient of λ to the power j okay.

Or in other words I would actually like to write it as, I will write down few terms. What we are actually saying is an λ to the power 0 which is equal to $1 + a_1 \lambda$ to the power 1, in general you can write as a_n to the power j λ to the power j okay. Now the important point here is for this to be operational, you will realize that if the λ has a dependence on time, it becomes very problematic alright, so that is the problem.

I mean it is very easy to say it like that, but what the thing we realize is that if you do this, then this expansion you have to understand, it is not definitely exact, it is very much of a stretch, but you have to see that this expansion were to be valid in this region and that region alone because there the λ is not changing as a function of time, it is as well could be λ equal to some C constant, right, that is exactly what is happening here and it is not valid in any small interval here.

This where it is suddenly getting turned on, but it is customary to introduce this λ , you will see it becomes a very convenient mathematically as less it allows us to make progress to equate these a_n s to or the coefficients to an exponentially observable parameters. So we will proceed forward with that. If you are not very comfortable, it is not, I mean I would not insist that we need to make this assumption or make this as a reality, but this just make you feel any comfortable, then you can think of this scenario.

Otherwise to imagine this as a switch that turns on and off the perturbation. In that scenario, everything holds good. Now, I have written down a power series expansion of the coefficients an of t in terms of λ the turning on parameter, the powers of the λ the turning on parameter. So now what we can do is that I can put this back into the equation number 5. Our equation number 5 is for a_k dot of t . So there, we are basically saying the $n = k$.

So we can write it as a_k dot of t is given by $\sum_j a_k^{(j)} \lambda^j$ which is equal to this a_n here we have to replace it again. So this a_n and if you have to do that with the power series expansion, so summation over n , I am going to use this term here which is the power series, a_n was 0 times λ to the power 0 + a_n of 1 λ to the

power 1 and so on times this term right, now the next term, this is the first term we finished alright.

Now the second term we are writing down, this everything remains the same, but the second term, the Hamiltonian here that Hamiltonian here had to be replaced by lambda times H right. So we have to do that. So the way we do that is $e^{ik} \lambda$ the perturbation Hamiltonian $e^{-i \Delta E_n T}$ by H cross right. Now we see that we have 2 polynomials here right, polynomial on the left hand side and then the polynomial on the right hand side and what we are going to do is that if you equate this, we have 2 polynomials.

One on the left hand side and one on the right hand side. Now what we can do is that we can equate the coefficients of the same powers of lambda right. So let me expand this in terms of this, so that you can see what I am actually referring to. So if you were to write down this in like term by term basis, then it can be written as $a_k \cdot$ right, see this is why it is important to have the lambda as independent of time right. So I can actually write it as a_k of dot the zeroth order times lambda to the power 0 which is 1 and $a_{k1} \lambda^1$ and so forth equals this whole term.

However, what you see is that this lambda is not being an operator it is a scalar can come out of this whole integral in which case what you will see is that that lambda gets multiplied here okay. So it is as if that each of these terms are multiplied by lambda as a result what we have is summation over n, see this summation is over the different eigenkets, different energy eigenkets right. So we have that intact still and what we have is an of 0, however now what we have is lambda to the power 0 times lambda which is actually $0 + 1$ is 1.

So every term or every lambda term gets a boost of +1 okay and you can write it as $e^{ik} \lambda$ perturbation Hamiltonian $e^{-i \Delta E_n T}$ over H cross. So now if you are thinking about, if you watch it carefully you have 2 polynomials right. Then the coefficients of this polynomial say $a_k \cdot$ and so forth, the coefficients of this polynomial should be equal for its powers which means first thing we realize is that a_{k0} that the zeroth order for the first one.

(Refer Slide Time: 18:57)

$$\begin{aligned}
\lambda^{(0)} \quad \dot{a}_k^{(0)} &= 0 \\
\lambda^{(1)} \quad \dot{a}_k^{(1)} &= \frac{-i}{\hbar} \sum_n a_n^{(0)} \langle e_k | H_1 | e_n \rangle e^{-iE_n t / \hbar} \\
&\vdots \\
\lambda^{(n)} \quad \dot{a}_k^{(n)} &= \frac{-i}{\hbar} \sum_n a_n^{(n-1)} \langle e_k | H_1 | e_n \rangle e^{-iE_n t / \hbar}
\end{aligned}$$

$|\psi\rangle^2 \rightarrow$ probability that you would find the system the ψ

Let us write down the first one. So equating lambda to the power 0 coefficients, on the left hand side we have \dot{a}_k on the right hand side we do not have any term with lambda to the power 0 which means the coefficient is actually 0 and the first order term for this we can go back and look at it that is this would be having coefficient drawn from this. So what we have is an summation over n an of 0 alright that is this and lambda goes away because we are equating the coefficients times $\langle e_k | H_1 | e_n \rangle$ this whole term $\langle e_k | H_1 | e_n \rangle$ the perturbation Hamiltonian H_1 to the power $-iE_n t / \hbar$.

I hope I have not missed any terms, so $\langle e_k | H_1 | e_n \rangle e^{-iE_n t / \hbar}$ so that is exactly the same term that we have written here. So like that we can go ahead and write down, so this is for lambda to the power 1. We can equate in general to lambda power n as \dot{a}_k somewhere here we have actually missed an i / \hbar term when we have canceled out here. So this would be actually \dot{a}_k of t^{-i} by \hbar cross alright. So that would carry on till here \hbar cross $-i$ by \hbar cross, so the same thing here, I forgot this term so $-i$ by \hbar cross so that would come in here too.

So $-i$ over \hbar cross, then we need to put that I mean we did not quite account for that. So $-i$ over \hbar cross, so equals $-i$ over \hbar cross times summation over n an the $n-1$ th order term $\langle e_k | H_1 | e_n \rangle$ to the power $-iE_n t / \hbar$, alright. So what do we have here? So what we have is that we can write down a general expression for the coefficient a_k okay except if we want to write down this coefficient a_k to an nth order, we need to know the coefficient, we need to be able to write down the coefficient to the $n-1$ order.

If you know this, then you would be able to write down the coefficients for the n th order or in other words we have a recursive, then if you want to know you have to go one step at a time back or one step at a time forward to keep getting this coefficient to a higher and higher order of accuracy, right because remember these a_0, a_1 are coming from this polynomial right, the polynomial that we did here okay, and so in this we have the a_n to the power j th order and this basically means that you are writing the a_n in terms to various different accuracies.

If you do not calculate these or in general if you were to restrict your a_n writing down till some n th term, then that is your accuracy. You could progressively increase your accuracy by going more and more in this direction or taking advantage of the fact that if you look at the real expression, it could be converging and then you can terminate it at reasonable limits of that is of use for all practical purposes. So that is the goal here right.

We could actually now write down an expression for the a_n to n th order of its accuracy in terms of e_k and e_n where e_n in general are the eigenkets of the unperturbed Hamiltonian and the perturbation Hamiltonian itself right. So you have let us say n different eigenkets, what you are actually having is you are forming a matrix of k by n and then this actually is a matrix element right, the $\langle e_k | H | e_n \rangle$ and if you write down this, we call it as a matrix element. Then we would know the a_n , that is fantastic.

So, now can we actually take it forward and make some related to laboratory measurement and then make some observations of what we will see, what property would have we missed if we did not go through this exercise, how do we do this? The first one we realize is that while a_n , this a_n basically double double of a_n are very convenient to write down the χ itself okay, but what we actually are interested is you can relate it to the measurable things, observable physical quantities is the fact that that what Born said that if you have a vector χ or vector ψ representing a state of a system.

Now what is the physical meaning of such vector. There are various different interpretation around, but the one that most of the people would agree on is called the Born's interpretation where he said that, thanks to Max Born, if you have a state vector sign represented by ket like this, then the modulus square of this okay modulus square of not this, it could actually if you have a state vector ψ and what Born said is you could take the modulus square and that

modulus square would tell you the probability that you would find the system in the state corresponding to χ .

So now this the χ here are the wave functions, so what it means is that how do we extract this modulus square from these a_k 's.

(Refer Slide Time: 29:33)

In order to do that what we are going to do is that, you can think of, I mean we have done that already right, to get the meaning out of this probability what we are actually after is you realize the modulus square of these a_k s alright and this I am going to state and we will in the next class say how I am stating that and we also see how we can actually calculate. The modulus square represents the probability of finding the system in state e_k having started from state e_g at $t = 0$.

So this will be coming from an initial condition, but I am going to just state this basically what we will see is that if we calculate the modulus e_k square right, modulus square of the e_k the coefficient, then that will be equivalent to the probability of finding the system in the state e_k having the system started from e_g the ground state okay. We will see in the next class how do we obtain this e_k coefficients or the modulus e_k square.

Also the reason why e_k square is really the probability and how is this statement, the e_k square, equating the e_k square to the probability comes directly from Born's interpretation of χ square a being the probability of you being able to find the system in a state kind, okay. Thank you and see you in the next class.
