Lecture 06
Special functions

Hello and welcome to the second week of this course on Mathematical Modelling and Simulation of Chemical Engineering Process. In this week we are going to study on various mathematical techniques that is indeed useful and necessary for solving different problems in process modelling and design.

(Refer Slide Time: 0:51)

CONCEPTS COVERED

- Legendre polynomials
- Bessel functions

So, first in this class, we will start with the special functions here, we are going to talk about mostly the legendary polynomials and the Bessel functions as these equations are quite commonly obtained in the solution to the ordinary as well as partial differential equations.

(Refer Slide Time: 1:18)

In the case of spherical co-ordinate systems,

$$(1-x) \frac{d^2 y}{dx^2} - 2x \frac{dy}{dx} + n(n+1)y = 0 \quad \leftarrow \frac{d}{dx} \left[(1-x)^n \right]$$

here $n \equiv$ non-negative integer
@ $x = \pm 1, y = 0$

$$y = C_1 P_n(x) + C_2 Q_n(x)$$

Legendre polynomial of first kind Legendre polynomial of second kind

Now, first talking about these legendary polynomials. In the case of spherical coordinate systems, you generally land up with the auxiliary equations, the auxiliary ordinary differential equations for a spherical coordinate partial differential system something like this. So, you can relate this equation to be the theta solution of the spherical Laplace equation. So, the analogue's form of this equation is obtained from something like this. So, here n is a non-negative integer. The boundary condition to this ODE is that x is equal to plus minus 1 you have y is equal to 0. Now, the generic solution to this equation is y equal to $C_1 P_n(x)$ plus $C_2 Q_n(x)$ where this P_n is the legendary polynomial of first kind and Q_n is the legendary polynomial of second kind.

(Refer Slide Time: 3:39)

Properties of P_n & Q_n

$P_n(1) = 1$ and $P_n(-1) = (-1)^n$

$\int_{-1}^1 P_n^2 dx = \frac{2}{2n+1}$

orthogonality $\int_{-1}^1 P_n P_m dx = 0$

Recursive relation,

$$P_n(x) = \frac{1}{2^n} \sum_{k=0}^n \binom{n}{k}^2 (x-1)^{n-k} (x+1)^k$$

So, $P_0(x) = 1$ $P_1(x) = x$ $P_2(x) = \frac{1}{2}(3x^2 - 1)$

$P_3(x) = \frac{1}{2}(5x^3 - 3x)$

$P_4(x) = \frac{1}{8}(35x^4 - 30x^2 + 3)$

So, now, coming to the properties of P_n and Q_n . So, $P_n(1)$ is equal to 1 and P_n (minus 1) is equal to minus 1 to the power n . Integration in properties in the domain of minus 1 to plus 1 if you do the square of integration with this one, it also satisfy the orthogonality condition as $\int_{-1}^1 P_n P_m dx = 0$, for $m \neq n$.

The recursive relation $P_n(x)$ is equal to, this is a generating function actually series solution a series in finance series in fact. In $\binom{n}{k}^2 (x-1)^{n-k} (x+1)^k$. So, from here you can easily understand that for different values of n , P_0 is 1, P_1 is equal to x , P_2 is a quadratic function, P_3 is a cubic function and so on, you can write P_4 the fourth order equation.

(Refer Slide Time: 5:52)

Also, $P_n(x) = \frac{1}{2^n n!} \frac{d^n}{dx^n} (x^2-1)^n$

Other important properties.

$$P_n(-x) = (-1)^n P_n(x)$$

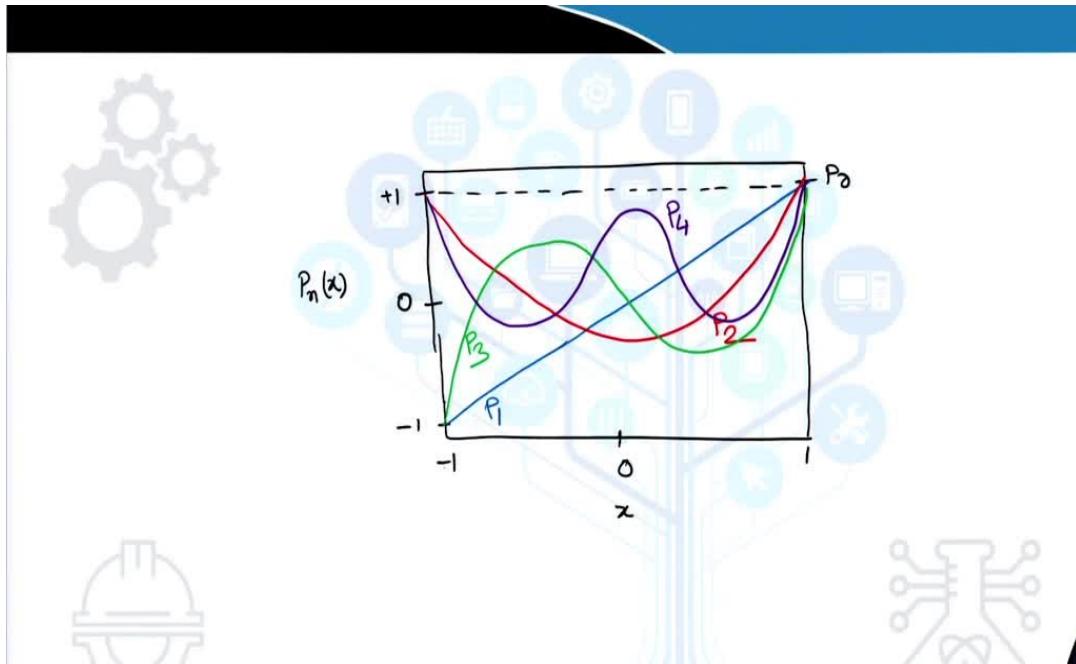

$$\int_{-1}^1 P_n(x) dx = 0 \quad \text{for } n \geq 1$$

recursive, $(n+1) P_{n+1}(x) = (2n+1)x P_n(x) - n P_{n-1}(x)$

differentiation, $\frac{x^2-1}{n} \frac{dP_n}{dx} = x P_n - P_{n-1}$

In the form of the differential, you can also write $P_n(x)$ as $1/2^n$ power, n factorial and n th derivative. Other important properties of the legendary polynomial of the first kind P_n of minus x is equal to, depending on the order of the polynomial, it takes this form. Integration does gives to 0 for n greater than or equal to 1 because P_0 is equal to 1. There is another recursive relation that if the values of n and n minus 1 you can calculate what is n plus 1 and this is one of the most useful relation here, $x P_n$. Differentiation property, x^2 minus 1 by n is $x P_n$ minus P_{n-1} . Also, you can write this is another important property I must write it here. So, if you take the derivatives of P_{n+1} and P_{n-1} that can give you also P_n .

(Refer Slide Time: 8:08)

Trying to draw the different curves of P , let us try to draw it, let us say this is the domain of x and here we try to write $P_n(x)$. I will try to make this hand drawing as precise as possible so, please bear with me. So, in the case of P_0 , it is constant 1. This is P_0 . Then we have this as P_1 , then P_2 is a quadratic function. So, this is P_2 . Then P_3 is a cubic function so, this is P_3 and P_4 is the fourth order polynomial. So, this is P_4 , and you can also draw P_5 and all.

(Refer Slide Time: 10:04)

Now, let us try to move into the secondary polynomial that is properties of Q_n . So, Q_n at the limits plus minus 1 is unbounded, and generally Q_n is related to P as in this form. So, if I am trying to draw the different Q curves, it will look something like this, please bear with me once again of my drawing. So, this is minus 1, 0, plus 1 this is x this is Q . So, here we have 0. So, this is almost tending towards minus infinity, and this is tending towards plus infinity. So, in the case of Q_0 since it is unbounded let us try to draw it.

So, it is better if I try to make the origin here so, this looks something this. So, this is Q_0 . Next let us try to draw Q_1 . So, Q_1 is so this is Q_1 , then sorry this is Q_2 , I made a mistake here Q_2 , and let me try to draw Q_1 for you. So, Q_1 is so this is Q_1 , Q_2 I have already drawn and Q_3 is... So, this is Q_3 and again simultaneously you can understand what Q_4 is. So, Q_4 would be leading to minus infinity on the minus side, in the minus one side and plus infinity on the plus side. So, let us try to look into some of the properties of Q .

(Refer Slide Time: 13:06)

$$Q_n(x) = \frac{1}{2} P_n \ln \left[\frac{1+x}{1-x} \right] - \sum_{k=0}^{\frac{1}{2}(n-1)} \frac{2n-4k-1}{(2k+1)(n-k)} P_{n-2k}$$

$$Q_0 = \frac{1}{2} \ln \left[\frac{1+x}{1-x} \right] \quad Q_1 = \frac{x}{2} \ln \left[\frac{1+x}{1-x} \right] - 1 \equiv P_1 Q_0 - 1$$

$$Q_2 = P_2 Q_0 - \frac{3}{2} x \quad Q_3 = P_3 Q_0 - \frac{5}{2} x^2 + \frac{2}{3}$$

$$Q_n(-x) = (-1)^{n+1} Q_n(x)$$

Recursive, $Q_{n+1}(x) = \frac{2n+1}{n+1} x Q_n - \frac{n}{n+1} Q_{n-1}$

So, Q_n is generally written down as an explicit formula provided P_n in this way. So, please bear with me it is the big formula this is the generating function for Q . But please understand that you need to have knowledge of P . So, from here you can easily estimate out what are your Q naught. So, Q naught is half $\ln 1$ plus x by 1 minus x and because of these logarithmic functions it is generally unbounded at plus and minus 1, and from here you can easily spot that this is nothing but equal to $P_1 Q_0$ minus 1.

So, similarly Q_2 is equal to $P_2 Q_0$ minus 3 by 2 x , Q_3 is going to $P_3 Q$ naught minus 5 by 2 x squared plus 2 by 3 it is all from generating function and Q_1 of minus x is in the same way but slight differences there is n plus 1 Q_n . Also you have the recursive relation, in this case too that is Q_{n+1} is equal to $2n+1$ by $n+1$ $x Q_n$, n by $n+1$ Q_{n-1} . So, if you know n and $n-1$ you can also know what the value at $n+1$ is.

(Refer Slide Time: 15:28)

The image shows a handwritten derivation of the Euler equation. It starts with the equation $x^2 \frac{d^2 y}{dx^2} + ax \frac{dy}{dx} + by = 0$. A note says "Euler equation". Below it, the generic solution is given as $y = x^r$. An arrow points from this to $y = 9$. The next step is to substitute $y = x^r$ into the equation, resulting in $x^2 \frac{d}{dx}(rx^{r-1}) + axr x^{r-1} + bx^r = 0$. This is then simplified to $x^2 r(r-1)x^{r-2} + arx^r + bx^r = 0$. A boxed equation shows $r(r-1) + ar + b = 0$. Finally, the quadratic formula is used to solve for r : $r = \frac{(1-a) \pm \sqrt{(1-a)^2 - 4b}}{2}$.

So, now moving to the next case of Euler equation and Euler equation is something which is generally encountered when you try to solve Laplace equation of r coordinate in spherical systems. So, the equation the auxiliary equations in really take this sort of ODEs and general generic solution to this equation is y equal to x to the power r . So, if you put a solution $y = x^r$ to the power r , you will see that it satisfies the Euler equation. How did I say it quickly instead of y I will write it to be x to the power r .

So, I am I have already done one derivation and one derivative that is $r x$ to the power r minus 1 plus $ax r x$ to the power r minus 1 plus $b x$ to the power r is equal to 0. We just do some algebraic steps here. So, if you do simply realize that $x r r$ minus 1, $x r$ minus 2 plus $a r x$ to the power r , plus b sorry x to the power r is always. So, if you divide both sides by x to the power r this is something you are going to get: $r r$ minus 1 from the first time then $a r$ plus b . Now, please understand that this is a quadratic equation in r which has 2 solutions, isn't it.

So, I can write the 2 solutions as r is equal to $\frac{1-a \pm \sqrt{(1-a)^2 - 4b}}{2}$. So, basically what it means is that instead the generic form can be extended to as y is equal to $C_1 x^{r_1}$ plus $C_2 x$ to the power r_2 where r_1 and r_2 are the solutions to this quadratic equation.

(Refer Slide Time: 18:00)

Bessel functions.

$$x^2 \frac{d^2 y}{dx^2} + x \frac{dy}{dx} + (x^2 - \alpha^2) y = 0$$

Generic solution: $y = C_1 J_\alpha(x) + C_2 Y_\alpha(x)$
 Bessel function of order α of 1st kind

Properties:

$$J_\alpha = \sum_{m=0}^{\infty} \frac{(-1)^m}{m! \Gamma(m+\alpha+1)} \left(\frac{x}{2}\right)^{2m+\alpha}$$

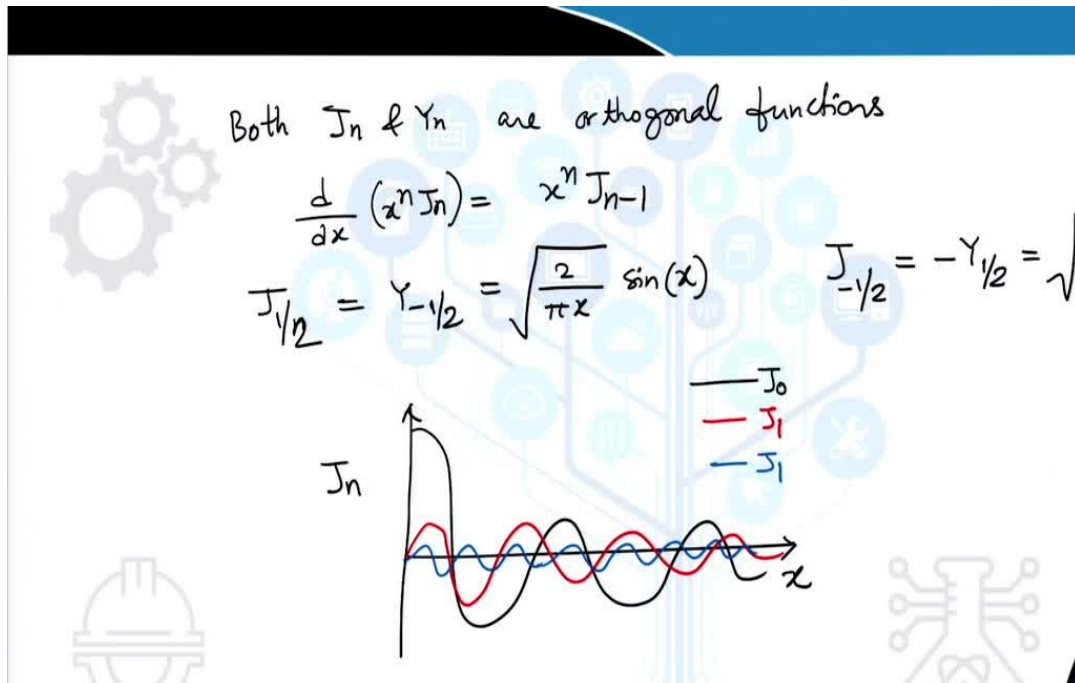

or $J_n(x) = \frac{1}{\pi} \int_{-1}^{+1} \cos(nz - x \sin z) dz$

$$J_{-n}(x) = (-1)^n J_n(x)$$

Now, moving towards the Bessel function. So, these Bessel functions are generally encountered in problems related to cylindrical coordinate systems whether you talk about distributed system in 1 dimensional or 2 dimensional, whatever in the case of multi-dimensional problem these are the auxiliary partial differential equations that you get from separation of variables otherwise, we will be getting them in the form of ODEs. So, how does the equation looks like $x^2 \frac{d^2 y}{dx^2} + \dots$ So generic solution to this ODEs is y is equal $C_1 J_\alpha$, this is the these are the Bessel functions and please note that these are the Bessel functions of order α of first kind.

So, this is Bessel function of order α of first kind. So, let us write some of the properties of J and Y . So, generally J_α is given down as an infinite series, this is the generating function. The gamma function and here you have $2m + \alpha$. Alternatively, you can write this way as $1/\pi$, some of the important properties J of $-n$ x is equal to $(-1)^n J_n(x)$.

(Refer Slide Time: 20:50)

Both J_n and Y_n are orthogonal functions. I leave it to you as an exercise to find out or to prove that these are orthogonal functions. In terms of derivatives this $\frac{d}{dx} x^n J_n$ would give you $x^n J_{n-1}$. Two important points about $J_{1/2}$ is the order. So, if I write $J_{1/2}$ and that is equal to $Y_{-1/2}$ and that is equal to $\sqrt{\frac{2}{\pi x}} \sin x$. Similarly, $J_{-1/2}$ is equal to $-Y_{1/2}$ and that is again equal to the cosine function.

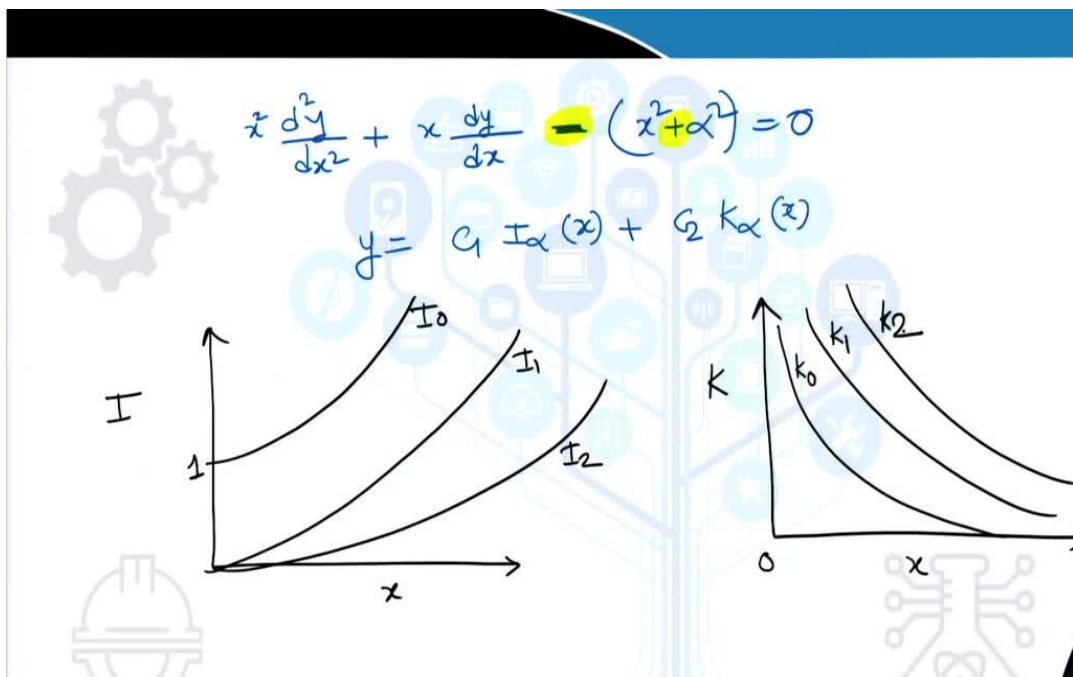

Now, trying to write down the situation for J , J versus x , so, this is J_0 then so, apart from J_0 all starts from 0, so, this is J_1 , so, this is J_1 , J_2 and the magnitudes of these derivative I mean this Bessel functions reduces. There are other integration and derivative properties of this J which you can look into any standard reference textbooks.

(Refer Slide Time: 23:02)

For the case of Y let us try to draw the case of I mean the plots for Y. Y let me just write this before we draw the curves. At x is equal to 0 it is unbounded. So, please keep this in mind. So, this is Y0. This is Y1, and this is Y 2.

(Refer Slide Time: 24:03)

Then moving next there is also possibility that you can have an equation where there is a minus sign in the last term, this is the minus sign. So, this is known as the modified Bessel function or Bessel this gives you the generic solution where they are of second kind. So, this is C1 I. So, the second kinds are given as I and K.

So, the previous one where the Bessel functions of first kind, this one we are getting here as the Bessel functions of second kind. So, please do not get confused because in many places we will see that this nomenclature is different. But essentially you will get the I and K functions when there is a negative sign in front of the third, I mean this is the important sign. Let me use a highlighter here.

So, this is the important part. So, if you get a negative sign here, then you are expected so, if there is a negative sign before the, this x square term the last x square term then you are getting the second kind equations, but if there is a positive term then you are going to get the first kind equation and let me show you the nature of the I and K functions. So, this is I0. It starts from 1 then all the remaining I actually starts from 0. K as you can easily interpret here from this plot that these are sort of hyperbolic in nature, but all are unbounded at x is equal to 0.

(Refer Slide Time: 26:25)

$$I_{\alpha}(x) = \sum_{m=0}^{\infty} \frac{1}{m! \Gamma(m+\alpha+1)} \left(\frac{x}{2}\right)^{2m+\alpha}$$

$$K_{\alpha}(x) = \frac{\pi}{2} \frac{I_{-\alpha} - I_{\alpha}}{\sin(\alpha\pi)}$$

$$I_{1/2} = \sqrt{2\pi x} \sinh(x)$$

$$K_{1/2} = K_{-1/2} = \sqrt{\frac{\pi}{2x}} \exp(-x)$$

The generating function for I is very similar to J but with slight difference of course. These are all in finite series. I hope you can spot the difference. The only difference is without the minus 1 to the power m factor. Similarly, for K this is related to again the I function. Fractional orders of the second kind functions like $I_{1/2}$ is given by the sin hyperbolic and the cos hyperbolic functions. I think one question I should pose here for you to find out whether these Bessel functions, I and K are orthogonal or not? Okay.

So, with this will close this lecture session in the next class we are going to talk about partial differential equations, it's classifications with different types, the technique of separation variables and so on. I hope you enjoyed the lecture today. Thank you.
