**Lecture -29**  
**Hermite's Differential Equation**

Welcome to the lectures in chemistry and the one the topic of atomic structure and chemical bonding. My name is Mangala Sunder and the I am in the Department of Chemistry Indian Institute of Technology as a professor of chemistry. The email ids are given below for you to write to me or for any other contact related to the course materials. This lecture is a follow-up on the last lecture on the infinite series representation and infinite series solution.

What is known as the power series solution for the differential equations. As the first serious example we shall look at the Hermite's differential equation, which is the basis for solving the harmonic oscillator problem and also getting the exact eigen functions.

(Refer Slide Time: 01:12)

So, please remember the 2 most important aspects of the last lecture on power series or 1.

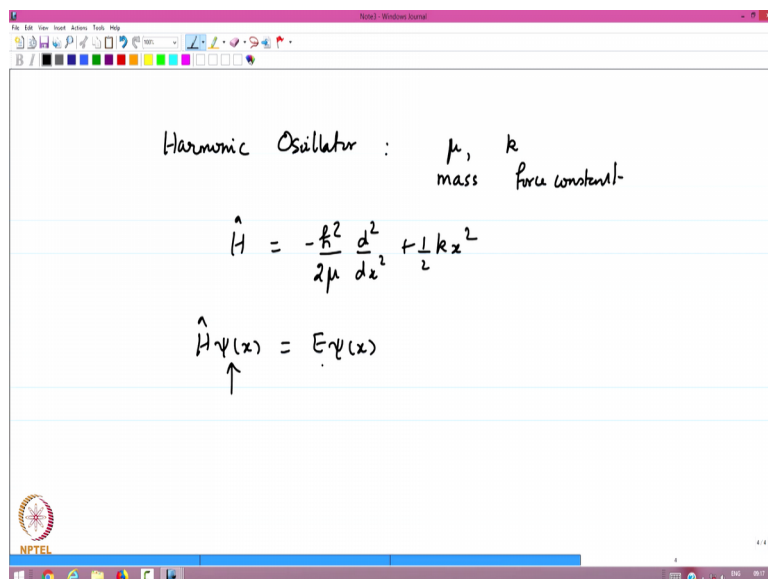

(Refer Slide Time: 01:20)

A proposal for the wave function solution, in terms of say in the case of 1 dimension as an x coordinate a solution in terms of an infinite series indexed by the integer n in x raise to n and then the second is a recurrence relation, which determines coefficients a n in terms of other coefficients.

In terms of a naught a 1 etcetera a 2 etcetera. So, these 2 things will be again the important aspects of today's this lecture on the Hermite's differential equation.

(Refer Slide Time: 02:15)

First let us recall the harmonic oscillator, Hamiltonian for a an oscillator with the mass mu and a force constant k, the Hamiltonian is minus H bar square by 2 mu d square by

dx square plus half kx square kinetic energy and the potential energy. Therefore, the solution that we are looking for is the H psi of x is equal to E psi of x, this is the differential equation and the solutions are psi and e.

(Refer Slide Time: 03:11)

mass force constant-

$$\hat{H} = -\frac{\hbar^2}{2\mu} \frac{d^2}{dx^2} + \frac{1}{2} kx^2$$

$$\hat{H}\psi(x) = E\psi(x)$$

$$\frac{d^2\psi(x)}{dx^2} + \left( \frac{2\mu E}{\hbar^2} - \frac{k\mu x^2}{\hbar^2} \right) \psi(x) = 0$$

constant:  $\lambda = \frac{2\mu E}{\hbar^2}$  ;  $\alpha^2 = \frac{k\mu}{\hbar^2}$

Therefore if we rewrite the differential equation we will have d square psi by d x square plus 2 mu e by h bar square minus k mu by h bar square x square psi of x is equal to 0 stay of x is equal to 0. Now let us introduce the constants, as introduced lambda as 2 mu E by h bar square and another constant alpha square as k mu by h bar square.

(Refer Slide Time: 04:03)

$$\frac{d^2\psi}{dx^2} + (\lambda - \alpha^2 x^2) \psi(x) = 0$$

Remove dimensional dependence, reduced equation

$x \rightarrow$  displacement

$$y = \sqrt{\alpha} x$$

$$\alpha^2 = \frac{\hbar\mu}{k} \Rightarrow \frac{mT^{-2}m}{(mL^2T^{-1})^2} = \frac{1}{L^4}$$

$\sqrt{\alpha} x = y$  dimensionless variable

Then the differential equation is  $\frac{d^2 \psi}{dx^2} + (\lambda - \alpha x^2) \psi = 0$ .

Now, the idea of writing different constants and also the equation in a different way is to remove the dimensional dependence and write a reduced equation using variables which do not have dimensions. Here please remember  $x$  has the dimension of the displacement that is the length of the oscillator from the equilibrium displacement from equilibrium therefore, there is a physical aspect of the harmonic oscillator which is part of the mathematics and then you have the Planck's constant  $\hbar$ , you have the energy which is also a dimension the quantity, the mass of the oscillator all these things are there which are specific to the oscillator itself.

Let us remove the oscillator specific details and we will write an equation which will be applicable to all oscillators independent about the masses and so on this is done in physics usually using dimensionless variables instead of the dimensional equation. So, let us introduce your dimensionless variable  $Y$  is equal to  $\sqrt{\alpha} x$  and see  $Y$  it is a dimensionless variable. If you recall the definition of  $\alpha$  it is  $\alpha^2 = \frac{k \mu}{\hbar^2}$ ,  $\alpha^2 = \frac{k \mu}{\hbar^2}$ ,  $k$  is the force constant the dimension of  $k$  is mass per square inverse mass times inverse square of time and the reduced mass  $\mu$  is also mass and  $\hbar^2$  leaving the angles out, it is basically mass length square  $T^{-2}$  minus 1 whole square because it is a square of the plancks constant.

So, the definition of  $\alpha^2$  is such that the dimension of  $\alpha^2$  is  $L^{-2}$  and  $L^{-4}$  because the other things cancel off. Therefore,  $\sqrt{\alpha} x$  if you define that as  $y$   $x$  having the dimension of the length and square root of  $\alpha$  being one by length  $y$  is dimension to the dimensionless variable. Therefore, to do that let us go back and write the differential equation again.

(Refer Slide Time: 07:01)

$$\frac{1}{\alpha} \frac{d^2 \psi}{dx^2} + \left( \frac{\lambda}{\alpha} - \alpha x^2 \right) \psi(x) = 0.$$

$$y = \sqrt{\alpha} x. \quad \frac{d}{dy} = \frac{1}{\sqrt{\alpha}} \frac{d}{dx}$$

$$\frac{y}{\sqrt{\alpha}} = x \quad = \left( \frac{d}{dx} \right) \frac{dx}{dy}$$

$$\psi \equiv \psi(x) \Rightarrow \bar{\psi}(y).$$

$$\frac{d^2 \bar{\psi}}{dy^2} + \left( \frac{\lambda}{\alpha} - y^2 \right) \bar{\psi}(y) = 0$$

D square psi by dx square times 1 by alpha plus lambda by alpha minus alpha x square psi of x is equal to 0 and then introduce now y is equal to root alpha times x, therefore, d by dy will be one by root alpha d by dx ok, d by dy is d by dx and dx by dy and you know x therefore, this is that.

So, the equation now becomes the function psi is a function of x. Now we replace x by y it is a different function, so let us call this a psi of y. Therefore, the differential equation this one becomes d square psi by dy square plus lambda by alpha minus y square psi of y is equal to 0. So, this is the differential equation in which the parameters related to the harmonic oscillators have all been removed, there is of course, lambda by alpha, but we will find that out. So, how to handle it, but the variable y is a dimensionless variable.

(Refer Slide Time: 08:38)

A screenshot of a Notepad window showing a handwritten differential equation. The equation is  $\frac{d^2 \bar{\psi}}{dy^2} + \left( \frac{\lambda}{\alpha} - y^2 \right) \bar{\psi}(y) = 0$  for  $y \in (-\infty, +\infty)$ . The equation is underlined. The window title is "Notepad - Windows Journal".

So, this differential equation namely this is valid for all values of  $y$  namely from minus infinity to plus infinity. So, in dealing with differential equations of this kind which take the entire range of real very real values the first is to look at the asymptotic solutions.

Asymptotic solutions refer to  $x$  going to plus or minus infinity large values. For very large here of course, is  $y$  that goes to plus minus infinity therefore, for very large values of  $y$  is possible to ignore this contribution which is a constant and write the differential equation as  $\frac{d^2 \bar{\psi}}{dy^2} - y^2 \bar{\psi} \approx 0$  and because  $\frac{\lambda}{\alpha}$  is much much less than  $y^2$  large  $y$ .

(Refer Slide Time: 09:47)

A screenshot of a Notepad window showing handwritten notes on asymptotic solutions. It includes the text "Asymptotic solution 1" with  $x \rightarrow \pm\infty$  large and  $y \rightarrow \pm\infty$ . Below this, the equation  $\frac{d^2 \bar{\psi}}{dy^2} - y^2 \bar{\psi} \approx 0$  is written, with the term  $\frac{\lambda}{\alpha} \ll y^2$  to its right. The equation is underlined. Further down, it says "An obvious - approximate:  $\bar{\psi} \sim e^{\pm \beta y^2}$ ". Below that, the differential equation is written as  $\frac{d^2 \bar{\psi}}{dy^2} = \pm 2\beta e^{\pm \beta y^2} + 4\beta y e^{\pm \beta y^2}$ , with the right-hand side terms underlined. The window title is "Notepad - Windows Journal".

And for this equation an obvious solution, an obvious I would say approximate solution is  $e^{\pm \beta y^2}$ . If we consider this  $\psi$  to be approximately of this form  $e^{\pm \beta y^2}$  then you can immediately write  $d^2 \psi / dy^2$  is plus or minus  $2\beta y$  it is a simple derivative.

So, let me write the result  $e^{\pm \beta y^2}$  plus four  $\beta^2 y^2 e^{\pm \beta y^2}$  minus  $y^2 \psi$ , that is this term and minus  $y^2 \psi$ . So, if you want to write to the differential equation with the this and that.

(Refer Slide Time: 11:11)

$$\frac{d^2 \psi}{dy^2} - y^2 \psi \approx 0$$

$$\Rightarrow [y^2(4\beta^2 - 1) \pm 2\beta] e^{\pm \beta y^2} = 0$$

$$y^2 = \mp \frac{2\beta}{(2\beta + 1)(2\beta - 1)}$$

$y \rightarrow \infty$      $2\beta = 1$   
 $y \rightarrow -\infty$      $2\beta = -1$   
 $\beta \sim \pm 1/2$

$e^{\pm \frac{1}{2} y^2} \rightarrow \infty \rightarrow$  Not a wave number  
 - Cannot be normalized

You will see that the equation that we have to write is  $d^2 \psi / dy^2 - y^2 \psi = 0$  goes over to the condition that  $y^2 = 4\beta^2 - 1 \pm 2\beta / y^2$  is equal to 0. This never goes to 0 except that infinity.

Therefore the solution that you have to look at is  $y^2 = 2\beta$  or  $y^2 = 2\beta + 1$  or  $y^2 = 2\beta - 1$ , this is also the here this is  $y^2$ . So, it is minus plus and the for  $y$  going to infinity; obviously,  $2\beta = 1$  and you can see that the solution  $\beta$  is plus minus half. It is  $y$  going to minus infinity of course, its  $2\beta = -1$ . Therefore, either way you have this, but the exponential function  $e^{\pm \frac{1}{2} \beta y^2}$  goes to infinity, therefore, it is not a wave function that we need or we would considered cannot be normalized.

(Refer Slide Time: 13:01)

$$\bar{\Psi}(y) \sim \underline{e^{-\frac{1}{2}y^2}} \quad \text{large } |y|$$
$$\bar{\Psi}(y) = \underline{H(y)e^{-\frac{1}{2}y^2}} \longrightarrow e^{-\frac{1}{2}y^2}$$
$$H \rightarrow \text{a polynomial as seen below.}$$
$$\bar{\Psi}(y) = H(y)e^{-\frac{1}{2}y^2}$$
$$\Rightarrow \frac{d^2 \bar{\Psi}}{dy^2} + \left( \frac{\lambda}{\alpha} - y^2 \right) \bar{\Psi} = 0$$

Therefore, let us take the solution  $\psi$  of  $y$  for large values of  $y$  to be  $e^{-\frac{1}{2}y^2}$  for large  $y$  absolute value of  $y$ , to plus minus  $y$  does not matter the function has the same value. What is the exact solution that we are looking for therefore,  $\psi$  of  $y$  is some function of  $y$  multiplied by  $e^{-\frac{1}{2}y^2}$  such that for very large values of  $y$  this function behaves like  $e^{-\frac{1}{2}y^2}$ . So, we need to introduce this function  $H$  and this  $H$  will turn out to be your polynomial as we will see soon. So, let us use this definition namely  $\psi$  of  $y$  as  $H$  of  $y$  times  $e^{-\frac{1}{2}y^2}$  and now consider the full differential equation  $\frac{d^2 \psi}{dy^2} + (\frac{\lambda}{\alpha} - y^2) \psi = 0$ .

(Refer Slide Time: 14:38)

$$e^{-\frac{1}{2}y^2} \left[ \frac{d^2 H}{dy^2} - 2y \frac{dH}{dy} + \left( \frac{\lambda}{\alpha} - 1 \right) H \right] = 0$$

Hermite:  $\frac{d^2 H}{dy^2} - 2y \frac{dH}{dy} + \left( \frac{\lambda}{\alpha} - 1 \right) H = 0.$

Objective: to determine H

$$H(y) = \sum_{n=0}^{\infty} a_n x^n$$

If you take the derivatives, you can see immediately this result namely  $e$  to the minus half  $y$  square times the second derivative of the function  $H$  minus  $2y$  the  $h$  by  $dy$  plus  $\lambda$  by  $\alpha$  minus  $1$   $H$ . This would be  $0$ , this is substituting this function in this equation. The differential equation that you get is the following and since this is valid for all values of  $y$  and this does not go to  $0$ , the differential equation known as Hermite's differential equation is this for  $1$   $d$  square  $H$  by  $dy$  square minus  $2y$   $d$   $H$  by  $dy$  plus  $\lambda$  by  $\alpha$  minus  $1$   $H$  is equal to  $0$  therefore, our objective is to find out  $H$  to determine  $H$ .

Now, for doing that let us propose  $H$  of  $y$  is a power series namely sum over  $n$  equal to  $0$  to infinity, sum constant  $a_n$  times  $x$  raised to  $n$ . So, at this point now you see that this is a starting point from the previous lecture on the power series therefore, this is a differential equation that we have to solve and this solution  $H$  if you recall is part of this solution namely the full solution the wave function is  $H$  of  $y$  multiplied by the Gaussian function  $e$  to the minus half  $y$  square therefore, the that the chain should be clear one should be able to follow the trails quite carefully.

(Refer Slide Time: 16:33)

$$H(y) = \sum_{n=0}^{\infty} a_n y^n$$

$$\frac{dH}{dy} = \sum_{n=1}^{\infty} n a_n y^{n-1}$$

$$\frac{d^2H}{dy^2} = \sum_{n=2}^{\infty} n(n-1) a_n y^{n-2}$$

$$\left[ 2a_2 + 2 \cdot 3 a_3 y + 3 \cdot 4 a_4 y^2 + \dots + (n+1)(n+2) a_{n+2} y^n + \dots \right]$$

$$- 2(a_1 y + 2 a_2 y^2 + 3 a_3 y^3 + \dots + n a_n y^n)$$

So, let us look at H of y given by this definition and then substitute the derivatives and the second derivatives and so on so. This is n equal to 0 to infinity a n x y raise to n, I am sorry it is not x it is y.

Where is to n and I think in the previous this is also y raise to n. d H by d y is the sum n equal to 1 to infinity n a n y n minus 1 and d square H by dy square is the second derivative namely n equal to 2 to infinity n into n minus 1 a n y n minus 2 ok. This we will substitute in the differential equation here a square H minus 2 yd H by dy this one. So, when you do that the substitution gives you the following, 2 a 2 plus 2 into 3 a 3 y plus 3 times 4 3 into 4 a 4 y square plus etcetera plus n plus 1 into n plus 2 a n plus 2 y raise to n plus etcetera.

This is the first term and this term is essentially this one, d square H by dy square. The next term is minus 2 d H by if you recall the next term is minus 2 y d H by d y therefore, d H by d y every term is multiplied by y to give you a 1 y plus 2 a 2 y square plus 3 a 3 y cube plus plus n a n varies to n and the last term is of course, the H itself multiplied by lambda by alpha minus 1.

(Refer Slide Time: 19:26)

$$+\left(\frac{\lambda-1}{x}\right)(a_0 + a_1 y + a_2 y^2 + \dots + a_n y^n + \dots) = 0$$

coefficient of  $y^n \quad n=0, 1, 2, \dots \Rightarrow 0$

coeff  $y^0 \quad 2a_2 + \left(\frac{\lambda}{x} - 1\right) a_0 = 0$

coeff  $y^1 \quad 3 \cdot 2 a_3 + \left(\frac{\lambda}{x} - 1 - 2 \cdot 1\right) a_1 = 0$

coeff  $y^2 \quad 4 \cdot 3 a_4 + \left(\frac{\lambda}{x} - 1 - 2 \cdot 2\right) a_2 = 0$

$y^n \quad (n+2)(n+1) a_{n+2} + \left(\frac{\lambda}{x} - 1 - 2 \cdot n\right) a_n = 0$

Therefore the last term is lambda by alpha minus 1, times H which is a naught plus a 1 y plus a 2 y square plus a n y raise to n plus so on is equal to 0.

As usual we will see that every term is either a constant or a power of y. So, we will equate each coefficient of y to the power n, n equal to 0, 1, 2, 3, etcetera, each one we will set it to 0 in order to obtain the solutions in final form therefore, the first term if you look at to the coefficient of y raise to 0 that is the constant term. If you look at you can see immediately that the terms are 2 a 2 there is no power of y here and then that is also lambda by alpha minus 1 times a 0. So, these are the only 2 terms without any y therefore, the first term is 2 a 2 plus lambda by alpha minus 1 a 0 is 0 and the coefficient of y to power 1 you can see it immediately here.

2 times 3 a 3 y minus 2 times 2 a 1 y and then there is a 1 y. So, again you can see this relation namely a 3 and a 1 are connected, a 2 and a 0 are connected and you can see this kind of odd even relationships and most of these equations coefficient of y 1 y raise to 1 namely coefficient of y itself is 3 time 2 a 3 plus lambda by alpha minus 1, minus 2 times 1 a 1 is equal to 0. So, let me write a couple of more coefficients here coefficient of y square is 4 times 3, a 4 plus lambda by alpha minus 1 minus 2 times 2 a 2 is 0 and likewise for the coefficient of y raise to n, the general term is n plus 2 into n plus 1 a n plus 2 plus lambda by alpha minus 1 minus 2 times n a n is equal to 0. N plus 2 and the n connected which means odd series and even series that you will have.

(Refer Slide Time: 22:27)

The image shows a digital whiteboard with the following handwritten equations:

$$a_2 = -\left(\frac{\lambda}{\alpha} - 1\right) \frac{a_0}{2}$$

$$a_4 = -\left(\frac{\lambda}{\alpha} - 1 - 2 \cdot 2\right) \frac{a_2}{3 \cdot 4} = \frac{(-1)^2 \left(\frac{\lambda}{\alpha} - 1 - 2 \cdot 2\right) \left(\frac{\lambda}{\alpha} - 1\right) a_0}{4!}$$

$$\downarrow$$

$$\boxed{a_{2n}} = \frac{(-1)^n \left(\frac{\lambda}{\alpha} - 1 - 2 \cdot (2n-2)\right) \left(\frac{\lambda}{\alpha} - 1 - 2(2n-4)\right) \dots \left(\frac{\lambda}{\alpha} - 1\right) a_0}{(2n)!}$$

Therefore the coefficient  $a_2$  is minus lambda by alpha minus 1 a naught by 2 and the coefficient  $a_4$  is minus lambda by alpha minus 1 minus 2 times 2 a 2 by 3 times 4, which is given as minus 1 whole square if you substitute for  $a_2$  from the above you get lambda by alpha minus 1 minus 2 times 2 times lambda by alpha minus 1 a naught divided by 4 factorial. The general term is  $a_{2n}$  is equal to minus 1 raise to n half is a 4 is minus 1 square a 2 is minus here a 2 is minus 1 raise to n lambda by alpha minus 1 minus 2 times 2 n minus 2 lambda by alpha minus 1 minus 2 times 2 n minus 4. All the way down to the last one when the n is 0, n is 2 you will see that lambda by alpha minus 1 times a naught divided by 2 n factorial.

This is the recurrence relation between all the even coefficients  $a_0$   $a_2$   $a_4$  etcetera all of them and of course, the odd coefficient if you follow the same mathematics it is immediate to write this down.

(Refer Slide Time: 24:20)

$$a_{2n+1} = \frac{(-1)^n}{(2n+1)!} \left[ \left( \frac{\lambda}{\alpha} - 1 - 2(2n-1) \right) \left( \frac{\lambda}{\alpha} - 1 - 2(2n-3) \right) \dots \right. \\ \left. \times \left( \frac{\lambda}{\alpha} - 1 - 2 \cdot 1 \right) \right] a_1$$

$$H(y) = \sum_{n=0}^{\infty} a_n y^n$$

$H(y) e^{-y^2/2}$   
 ↑ faster      ↓ decreasing  
 Rate of increase of  $H(y)$

So, the coefficient  $a_{2n+1}$  is related to the coefficient  $a_1$  by the formula, exactly the same way as above minus 1 is  $2n+1$  factorial times  $\lambda$  by  $\alpha$  minus 1 minus 2 times  $2n-1$   $\lambda$  by  $\alpha$  minus 1 minus 2 times  $2n-3$  all the way to  $\lambda$  by  $\alpha$  minus 1 minus 2 into 1 times  $a_1$ . Therefore, you have the relationship of  $a_1$  to  $a_3$   $a_5$   $a_7$ , etcetera and the relationship of  $a_1$  to  $a_2$   $a_4$   $a_6$ , etcetera.

So, therefore, we know the  $H$  of  $y$  as an infinite series. The difficulty is that  $H$  of  $y$  is multiplying  $e$  to the minus  $y$  square by 2, it is important that  $H$  of  $y$  does not increase faster than  $e$  to the minus  $y$  square decreasing or at least the same as the rate. The rate of increase of  $H$  of  $y$  term by term if you look at it, it should be faster, it should not be even the same as that of this one because then the series will not converge, the product will not converge to give you a finite wave function, a the square of the wave function should go to a finite value when you integrate.

(Refer Slide Time: 26:28)

$$\int_{-\infty}^{\infty} \psi(x)\psi(x) dx = 1$$

$$\frac{a_{n+2}}{a_n} = \frac{-(\frac{\lambda}{\alpha} - 1 - 2n)}{(n+1)(n+2)} \sim \frac{2n}{n^2} \sim \frac{2}{n}$$

$e^{-y^2} \rightarrow \text{decreases} \rightarrow \frac{2}{n}$

Hermite series should be truncated to finite terms.

Remember ultimately we have to have this property  $\int \psi(x)\psi(x) dx$  from minus infinity to plus infinity this should be normalized to 1, if this tends to infinity then this function is not very good.

Take a quick look at  $a_{n+2}$  if you take the ratio to  $a_n$  then you will see that the term is  $\frac{\lambda/\alpha - 1 - 2n}{(n+1)(n+2)}$ . So, this is of the order when  $n$  is very very large  $\lambda/\alpha - 1$  is irrelevant, this is of the order  $2n/n^2$  and the other terms can also go to they can be removed because the  $n$  is very large  $n^2$  is the leading term. So, it is  $2/n$ . The unfortunate thing is  $e^{-y^2}$  also decreases in the same order  $2/n$ .

So, we have a problem if we take these two together that this function will not be a Hermite polynomial, Hermite function the infinite series is not the right solution, but the Hermite function series should be truncated to finite terms. Only then the product function will be acceptable as a wave function for the harmonic oscillator problem.

(Refer Slide Time: 28:11)

Hermite: polynomial.

for some  $n$ ,  $a_n \neq 0$   
 $a_{n+1}, a_{n+2}, \dots = 0$ .

$$H(y) = \sum_{n=0}^{\text{finite } n} a_n y^n$$

$\frac{\lambda}{\alpha} - 1 - 2n = 0$  for some  $n$ .  
 $\frac{\lambda}{\alpha} - 1 = 2n$

$$H(y) = a_0 \left[ 1 - \left(\frac{2n}{2}\right) y^2 + \frac{(2n)(2n-4)}{4!} y^4 - \frac{(2n)(2n-4)(2n-8)}{6!} y^6 + \dots \right]$$

So, if you have to truncate this function then Hermite series should be a polynomial. What it means is that for some  $n$  a  $n$  may not be 0, but all the other terms  $a$  and plus 1 a  $n$  plus 2 all these coefficients should be 0 then the series is truncated to a finite value then you can write  $H$  of  $y$  as  $n$  equal to 0 to some finite  $n$  a  $n$   $y$  raise to  $n$ . This will be the requirement in order for the wave function to be normalizable. So, if you have to make this to a finite value that is the right the  $H$  of  $y$  based on the  $a_n$  s we have written down so far the even terms are all  $a_n$   $1 - 2n$  by  $2$   $y$  squared plus  $2n - 4$  by  $4$  factorial  $y$  raise to 4 and so on. So, what we have assumed is that  $\lambda$  by  $\alpha$  minus 1 minus  $2n$  is 0 for some  $n$  and therefore,  $\lambda$  by  $\alpha$  minus 1 is equal to  $2n$  that is put in here.

Then you have let me write the next term for the series minus  $2n$  times  $2n - 4$  times  $2n - 8$  divided by  $6$  factorial  $y$  raise to 6 plus etcetera, this is the even number of terms.

(Refer Slide Time: 30:13)

$$+ a_1 \left[ y - \frac{(2n-2)}{3!} y^3 + \frac{(2n-2)(2n-6)}{5!} y^5 - \frac{(2n-2)(2n-6)(2n-10)}{7!} y^7 + \dots \right]$$

$a_0, a_1$  are chosen so that the last  $y^n$  term

even  $n \Rightarrow a_0 = (-1)^{n/2} \frac{n!}{(n/2)!}$

for odd  $n \Rightarrow a_1 = (-1)^{(n-1)/2} \frac{2(n!)}{\left(\frac{n-1}{2}\right)!}$

And the odd coefficients are all connected to a 1 they will be  $y$  minus  $2n$  minus  $2$  by  $3$  factorial  $y$  cube plus  $2n$  minus  $2$  times  $2n$  minus  $6$  by  $5$  factorial  $y$  raise to  $5$  minus  $1$  more term I will write  $2n$  minus  $2$   $2n$  minus  $6$   $2n$  minus  $10$  divided by  $6$  factorial  $y$  raise to  $7$  plus etcetera. But it is truncated to the value  $n$ , what is the value of  $n$ ?  $n$  can be  $0$ ,  $n$  can be  $1$ ,  $n$  can be  $2$  each  $n$  gives you 1 Hermite polynomial. So, the truncation is important in the sense that the physical parameters  $\lambda$  by  $\alpha$ .

So, let me highlight these the physical parameters are there in  $\lambda$  and  $\alpha$ , remember  $\lambda$  was given in terms of if you go back to the lecture very early on, you can see what was the definition of  $\lambda$ . From the differential equation we had put in  $\lambda$  is equal to  $2\mu e$  by  $\hbar$  square. So, here is the physical constant and  $\alpha$  is  $k\mu$  by  $\hbar$  square. So,  $\lambda$  and  $\alpha$  for determine the physical parameters and the physical parameters are chosen such that this condition is approximately valid  $\lambda$  by  $\alpha$  minus  $1$  is  $2n$  then the Hermite polynomial is truncated to the last term, only to that term.

And the convention is to choose for Hermite polynomials the constants  $a_0$  and  $a_1$  are chosen so that the maximum term, so that the last  $y$  raise to  $n$  term, has the coefficient as follows. For even  $n$   $a_0$  is chosen as  $(-1)^{n/2} n!$  by  $(n/2)!$  factorial and for odd  $n$  is possible for us to write this. This is a convention in the choice of the Hermite's solution  $a_1$  is written as  $(-1)^{(n-1)/2} 2(n!)$  by  $((n-1)/2)!$  factorial. This is the highest term that is the  $y$  raise to  $n$  th term therefore, with this convention now we can write the Hermite polynomial as follows.

(Refer Slide Time: 33:27)

The image shows a digital whiteboard with handwritten mathematical expressions for Hermite polynomials. The expressions are:

- $n=0$   $H_0(y) = 1$  ←  $a_0$
- $n=1$   $H_1(y) = 2y$  ←  $a_1$
- $n=2$   $H_2(y) = 4y^2 - 2$  ←  $a_0, a_2$
- $n=3$   $H_3(y) = 8y^3 - 12y$  ←  $a_1, a_3$
- $n=4$   $H_4(y) = (12 - 48y^2 + 16y^4)$  ←  $a_0, a_2, a_4$
- $n=5$   $H_5(y) = 120y - 160y^3 + 32y^5$  ←  $a_1, a_3, a_5$

A green bracket on the left side of the whiteboard groups all these equations together. The whiteboard interface includes a toolbar at the top and an NPTEL logo at the bottom left.

The first Hermite polynomial namely when  $n$  equal to 0 the  $H_0$  of  $y$  will become 1 ok, it is just a naught.

Which you can see right away, that if  $n$  is 0 all of this gets to 1, 0 factorial is 1. If you choose  $n$  equal to 1 the  $H_1$  of  $y$  will give you the value  $2y$ , which is also easy to see, you are only retaining the first term you are not keeping because now  $n$  is limited only to 1 therefore, when  $n$  is 2 this term goes to 0 all the other terms go to 0. So, when  $n$  is 1 you have the odd  $n$  here minus 1 raise to  $n$  minus 1 to  $n$  factorial is 1 and then you have  $n$  minus 1 by 2 factorial that is also 1. So, you have 2 therefore, the coefficient  $a_1$  is 2 and therefore, the expression is  $2y$ . So, likewise  $n$  equal to 2  $H_2$  of  $y$  becomes  $4y^2$  minus 2  $n$  equal to 3  $H_3$  of  $y$  becomes  $8y^3$  minus  $12y$ .

You see that this means a naught this also means a naught and a 2 and let me write 1 more term  $n$  equal to 4  $H_4$  of  $y$  is equal to  $12$  minus  $48y^2$  plus  $16y^4$ , this means only these 3 coefficients a naught, a 2 and a 4 are chosen and  $n$  has the value and  $y$   $n$  equal to 5 is the last term. I will write  $H_5$  of  $y$  which is  $120y$  minus  $160y^3$  plus  $32y^5$  and all these numbers come from the choice of those things therefore, this you can see now this is a 1 this is the choice of a 1 and a 3 this is the choice of a 1, a 3 and a 5. So, the Hermite polynomials are such that you see that the reason even polynomial the reason odd polynomial depending on which constant you choose and these coefficients are connected by the recurrence relations that we had earlier. This is the recurrence

relation that we had and in this therefore, we have chosen the condition that lambda by alpha minus 1 is equal to 2 n. So, when n is 0 of course, you get a 0 when n is 1 you get a 1 and so on therefore, what is the final solution now?

(Refer Slide Time: 36:29)

The image shows a whiteboard with the following handwritten equations and text:

$$\bar{\Psi}_n(y) = e^{-y^2/2} H_n(y) \quad n=0, 1, 2, \dots$$

$$\left(\frac{\lambda}{\alpha} - 1\right) = 2n$$

$$\lambda = \frac{2\mu E}{\hbar^2} \quad \alpha = \sqrt{\frac{k\mu}{\hbar^2}}$$

$$\frac{\lambda}{\alpha} = \frac{2\mu E}{\hbar^2} \times \frac{\hbar}{\sqrt{k\mu}} = 2n+1$$

$$E = \left(\frac{2n+1}{2}\right) \times \hbar \times \left(\sqrt{\frac{k}{\mu}}\right) \quad \omega \text{ angular frequency for the oscillator}$$

The final solution psi of y is e to the minus y square by 2 H n of y and since n is chosen as 0, 1, 2, 3, etcetera subject to the condition lambda by alpha minus 1 is equal to 2 n. Now let us look at lambda remember lambda is 2 mu E by h bar square and alpha is equal to alpha square was chosen as k mu by h bar square and alpha therefore, is basically square root of k mu by h bar square therefore, what is lambda by alpha if you do that its 2 mu e by h bar square into h bar divided by square root of k mu. So, you have mu to the one half this mu is gone and what is left over you have a h bar is gone.

H bar square you have a h bar down here therefore, lambda by alpha turns out to be 2 mu to the one half E by k to the one half and h bar and that is lambda by alpha and that is equal to 2 n plus 1. Therefore, what is E? E is equal to 2 n plus 1 into h bar into square root of k by mu divided by 2 and square root of k by mu you know is the angular frequency for the harmonic oscillator, for the oscillator.

(Refer Slide Time: 38:42)

$$E = \frac{(2n+1)}{2} \times \hbar \times \sqrt{\frac{k}{\mu}}$$

$$E = (n + \frac{1}{2}) \hbar \omega = (n + \frac{1}{2}) h \nu$$

Harmonic  
 $n = 0, 1, 2, 3.$   
 $\psi_n = H_n(y) e^{-y^2/2}$

Therefore what you have is the energy  $E$  now in terms of the  $n$  values that you have chosen,  $E$  is given as  $n$  plus a half  $\hbar \omega$ , which is the same as  $n$  plus a half  $h \nu$  since  $\omega$  is equal to  $2\pi \nu$  and  $\hbar$  is  $h$  by  $2\pi$  therefore, they cancel out when you take the product of these 2.

So, you see that the energy expression for the harmonic oscillator is now given in terms of the  $n$  plus a half where the possible values of  $n$  or 0, 1, 2, 3 etcetera and the wave function  $\psi_n$  corresponding to this  $e^{-y^2/2}$  or this  $n$  is; obviously,  $H_n$  of  $y$  to the minus  $y^2$  by 2. So, this is the sum and substance of the harmonic oscillator problem that we have the rest of it of course, I have already discussed in the harmonic oscillator model, how to normalize these functions and how to visualize the wave function as well as the square of the wave function and so on. Therefore, now you can connect to this let me leave you with the last conversion namely remember  $y$  is equal to  $\sqrt{\alpha} x$ .

(Refer Slide Time: 39:50)

$y = \sqrt{\alpha} x$   
 $\psi(x) = H_n(\sqrt{\alpha} x) e^{-\alpha x^2 / 2} N_n$   
 $\int_{-\infty}^{\infty} \psi(x) \psi(x) dx = 1$   
 $N_n = \sqrt{2^n n! \sqrt{\pi} / \alpha}$

Therefore the wave function that we are talking about psi of x is now in terms of the variables that we have here it is H n of root alpha x and e to the minus alpha x square by 2.

The only thing that is missing is the normalization constant n such that psi of x psi of x integral d x psi star is of course, these are all real functions or we do not need to worry about the stock this is equal to 1. Therefore, you can calculate N of n and the general expression for N of n when you do the mathematics is also available and let me write that down. The general expression for N is 2 raise to n n factorial times root pi by alpha the whole square root that is the general factorial and therefore, you can see that the harmonic oscillator wave function, the harmonic oscillator energies are all obtained from the very simple differential equation namely the Hermite differential equation.

So, this whole exercise is to actually take you through the mathematics as in as detailed a manner as possible without worrying too much about to be the mathematical properties of some of these terms. But remember where the series comes from the series comes from the fact that the Hermite the infinite series is truncated to give a finite polynomial and the truncation means you truncate at various powers of n and various values of n.

Therefore you get a whole series of polynomials. What is the maximum value of n, n can go up to infinity all it means is that the harmonic oscillator will remain as a harmonic oscillator even for extremely large values of x, but that is a mathematical limit. Molecules do not oscillators do not they all become an harmonic even after a small

amplitude therefore, these functions are important in understanding the one important part of the analytics analytical solution to the economic chemical problem namely the differential equation for the harmonic oscillator and the Schrodinger equation.

We will see only one more such equation namely the spherical harmonics which is also very important for all the angular momentum problems and therefore, I will take you through the infinite series solutions for the Legendre. And the associated Legendre polynomials in the next lecture and with that this part of mathematics is to give you a feel that things are not hands or I mean they are not you do not wave your hands, but you actually sit down and do the mathematics carefully.

Thank you very much.
