Lecture – 34
Spin Angular Momentum and Coupling of 2 Spin-1/2 Angular Momenta

Welcome back, to the lectures in Chemistry and to the Atomic Structure and Chemical Bonding. My name is Mangala Sunder, I am in the Department of Chemistry IIT, Madras and my e-mail addresses are given here, the coordinates are here for you to communicate to me.

The lecture continues from what I left in the previous one, the Properties of Spin Angular Momentum. We saw in the previous lecture the spin half angular momentum and we looked at the Pauli spin matrices, the relation that we have with the Pauli spin matrices, the commutation relation and the anti commutation relations, all those things were explained the bit and in this lecture, we continue with the same. But now with integer angular momenta and higher angular momenta namely not spin half systems, but spin 1, spin 3 halves a little bit of that before we proceed to the understanding of the interactions between 2 spin half systems in this course. Of course, the importance is to the interaction between two electrons or two angular momenta of two spin one half systems.

(Refer Slide Time: 01:45)

Pauli spin $\frac{1}{2}$ matrices.

$$\begin{aligned}\sigma_x \sigma_y + \sigma_y \sigma_x &= 0 \\ \sigma_y \sigma_z + \sigma_z \sigma_y &= 0 \\ \sigma_z \sigma_x + \sigma_x \sigma_z &= 0\end{aligned}$$
$$\sigma^2 = \sigma_x^2 + \sigma_y^2 + \sigma_z^2 = 3 \mathbb{1}_{2 \times 2}$$
$$\mathbb{I}_x = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \frac{1}{2} \sigma_x$$
$$\mathbb{I}^2 = \frac{1}{4} \sigma^2 = \frac{3}{4} \mathbb{1}_{2 \times 2} = \frac{3}{4} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Let me first restate or recall what we wrote down in the last couple of minutes of the last lecture, we did $\sigma_x \sigma_y + \sigma_y \sigma_x$ Pauli spin matrices spin one half matrices that is equal to 0 and likewise for $\sigma_y \sigma_z + \sigma_z \sigma_y$ and $\sigma_z \sigma_x + \sigma_x \sigma_z$ is equal to 0 and then we had σ^2 as $\sigma_x^2 + \sigma_y^2 + \sigma_z^2$. And that is 3 times the identity matrix 2 by 2. But, recall that then we wrote down the spin angular momentum operator I_x we had it as $\frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and therefore, this was written as $\frac{1}{2} \sigma_x$.

Therefore, if you are looking at I^2 then essentially it is $\frac{1}{4} \sigma^2$, therefore, it is $\frac{3}{4}$ times the identity matrix 2 by 2 namely $\frac{1}{4} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$. This is the spin half angular momentum, this is the Pauli representation of the angular momentum spin half in terms of matrices, the relation between the two is given by this numerical factor one half, I think that is important to remember.

(Refer Slide Time: 03:29)

Handwritten notes on a whiteboard:

$$I_+ |\beta\rangle = |\alpha\rangle \quad I_- |\alpha\rangle = |\beta\rangle$$

Generalized: $|\alpha\rangle = \left| \frac{1}{2} \frac{1}{2} \right\rangle$ $I^2 |\alpha\rangle = \frac{1}{2} \left(\frac{1}{2} + 1 \right) |\alpha\rangle$
 $|\beta\rangle$ $|\beta\rangle$

$$I_z |\alpha\rangle = \frac{1}{2} |\alpha\rangle$$

$$|\beta\rangle = -\frac{1}{2} |\beta\rangle$$

$I = 1, \frac{3}{2}, 2, \frac{5}{2}, 3, \dots$ nuclear spins as well.

Now, also recall the properties that when we wrote down I_+ on beta we had it as alpha and I_- on alpha is equal to beta. These things can be generalized the angular momentum properties of I_+ and I_- on any spin angular momentum states can be generalized to the following relations. Recall that when we wrote down alpha as a state it was the quantum numbers half and half corresponding to the I^2 on alpha or beta giving you half into half plus 1 which is what was written as $\frac{3}{4}$ times alpha times beta and I_z on alpha and beta.

(Refer Slide Time: 06:58)

The image shows a handwritten slide with the following content:

$$I_+ |I m\rangle = \sqrt{(I-m)(I+m+1)} |I m+1\rangle$$

$$I_- |I m\rangle = \sqrt{(I+m)(I-m+1)} |I m-1\rangle$$

$$I_+ |I I\rangle = 0, \quad I_- |I -I\rangle = 0$$

$$m = -I, -I+1, \dots, I-1, I$$

Below the equations is a ladder diagram consisting of horizontal lines representing energy levels. The top level is labeled $|II\rangle$ and the bottom level is labeled $|I-I\rangle$. Upward arrows connect the levels from $|I-I\rangle$ to $|II\rangle$, and downward arrows connect the levels from $|II\rangle$ to $|I-I\rangle$.

Now, what about the I_+ on $I m$? This can be obtained in general and I am going to give you the relation namely, it is $I - m$ into $I + m + 1$ square root $I m + 1$ and likewise I_- on $I m$ is square root of $I + m$ and $I - m + 1$ $I m - 1$. One way to remember this combination whether it is a plus or minus in the first term is to recall the fact that I_+ on $I I$ the highest state is 0 and I_- on the lowest state $I - I$ is 0 this is the m value, these are the m value.

So, m takes the value minus I , minus $I + 1$, $I - 1$, I this is what you had for a spin the half it was very easy this was a minus half and this was a plus half there were only two states because minus $I + 1$ stopped with I . Therefore, for a spin half system the I_+ on I was essentially I_+ on half that was 0, and you can see that right away that I_- on m ensures that m never exceeds I , m never exceeds I . Therefore, if you were to arrange the states in some ladder form then in the ladder the lowest is $I - I$ and the highest is $I I$ and the I_+ operator takes it up and the I_- operator takes it down, but there is nothing below the lowest and there is nothing above the highest.

So, it is easy to remember that the moment you remember $I - m$ you can immediately recall that it is $I + m + 1$ so, some way of numeric form to recall and remember important relations.

(Refer Slide Time: 09:06)

The image shows a whiteboard with handwritten mathematical equations. The first equation is $I_x |I_m\rangle = \frac{1}{2}(I_+ + I_-) |I_m\rangle$. The second equation is $= \frac{1}{2} \left[\sqrt{(I-m)(I+m+1)} |I, m+1\rangle + \sqrt{(I+m)(I-m+1)} |I, m-1\rangle \right]$. The third equation is $\langle I_m | I_m' \rangle = \delta_{mm'}$. The fourth equation is $\langle I_m' | I_x | I_m \rangle = \frac{1}{2} \left[\delta_{m+1, m'} \sqrt{(I-m)(I+m+1)} + \delta_{m-1, m'} \sqrt{(I+m)(I-m+1)} \right]$. The whiteboard also shows a Windows taskbar at the bottom and a toolbar at the top.

Therefore, if you were to write on I_x the action of I_x on I_m it is $\frac{1}{2}$ of I_+ plus I_- on I_m . Thus the answer would be $\frac{1}{2}$ square root of $I-m$ times $I+m+1$ plus $\frac{1}{2}$ square root of $I+m$ times $I-m+1$ on the state $I, m-1$. That is the matrix, that is the action of the operator on the state I, m . Therefore, the state I, m is not an Eigen function of the operator I_x the same way like the Pauli spin matrix that is the I_x was not giving you the Eigen value for the alpha state or the beta state it gives you $I, m+1$ or $I, m-1$.

So, let me just highlight that alone. So, the state I, m when it is acted on by I_x gives you $I, m+1$ or $I, m-1$. Therefore, recalling that the states I, m and I, m' are orthogonal $\delta_{mm'}$ it is immediately possible for us to write that if I write I, m' I_x on I, m I will get the result namely $\delta_{m, m'} \sqrt{(I-m)(I+m+1)}$ plus $\delta_{m-1, m'} \sqrt{(I+m)(I-m+1)}$. And here the m' is what? The m here is $m+1$ or $m-1$ because the m' has to be equal to this in order for I_x on I, m which gives you $I, m+1$ to be nonzero. Therefore, m' so, this I, m' will recover this $I, m+1$ on the action of I_x on I, m provided this m' is equal to $m+1$, that is what this is the part.

Now, what about this term? This term tells you that if m' ; let me use a different label, if m' were equal to $m-1$, then $m-1$ will be recovered. So, the

second term that you will get is $\delta_{m' m} \sqrt{l(l+1) - m(m \pm 1)}$.

(Refer Slide Time: 12:48)

$\langle I_{m'} | I_x | I_m \rangle \quad m' = m \pm 1$

Spin 1

Spin 1

$\langle 11 $	$\langle 10 $	$\langle 1-1 $	
$\langle 11 I_x 11 \rangle$	$\langle 11 I_x 10 \rangle$	$\langle 11 I_x 1-1 \rangle$	$I_x = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$ $\frac{1}{2} \begin{pmatrix} 0 & \sqrt{2} & 0 \\ \sqrt{2} & 0 & \sqrt{2} \\ 0 & \sqrt{2} & 0 \end{pmatrix}$
$= 0$	$= 0$	$= 0$	
$\langle 10 $	$\langle 10 I_x 11 \rangle$	$\langle 10 I_x 10 \rangle$	
$\langle 10 I_x 10 \rangle$	$\langle 10 I_x 1-1 \rangle$		
$= 0$	$= 0$		
$\langle 1-1 $	$\langle 1-1 I_x 11 \rangle$	$\langle 1-1 I_x 10 \rangle$	
$\langle 1-1 I_x 11 \rangle$	$\langle 1-1 I_x 10 \rangle$	$\langle 1-1 I_x 1-1 \rangle$	
$= 0$	$= 0$	$= 0$	

So, the matrix elements of this quantity I_x , if I have to write the general operator $I_{m' m}$ the matrix elements of this operator I_x or nonzero provided m' is equal to $m \pm 1$, those are the only two possibilities. If m' is equal to $m + 1$, this is the matrix element. If m' is equal to $m - 1$, this is the matrix element. Therefore, if you write this in the matrix notation generally I for example, let us write this for spin 1.

If we write this for spin 1, the I_m will be $1, 1, 1$ and the states are $1, 0, 1$ minus 1. Now, this element is $1, 1, I_x, 1, 1$, this is 0 because the two states are identical. This element is $1, 1, I_x, 1, 0$. This is not 0 because m' is equal to $m - 1$ because there is a plus component of this which will raise 0 to 1 and therefore, this element is nonzero. But, on the other hand this will be 0 because here m' minus 1 is not $m \pm 1$, but it is actually 2 off. So, this is 0, this is nonzero and likewise you have $1, 0, I_x, 1, 1$ this is nonzero $1, 0, I_x, 1, 0$, this is 0, $1, 0, I_x, 1$ minus 1, this is nonzero and likewise 1 minus 1 $I_x, 1, 1$ this is 0, 0 this is nonzero 1 minus 1 $I_x, 1, 0$ and then the diagonal element 1 minus 1 $I_x, 1$ minus 1 this is 0.

So, for a spin one if you calculate these things using the formula you must get the operator representation the matrix representation of the operator will turn out to be 1 by

root 2, 0 1 0, 1 0 1, 0 1 0. This 1 by root 2 is basically 1 by 2 and the matrix elements that you calculate will all be root 2 0 2 0 root 2. So, I have cancelled the root 2 to give you this. This is what you will get, this is what you will get from this calculation. So, this is what I x, what about I y?

(Refer Slide Time: 15:54)

The image shows a whiteboard with the following handwritten content:

$$I_y = -\frac{i}{2}(I_+ - I_-)$$

$$\langle I_{m+1} | I_y | I_m \rangle = -\frac{i}{2} \langle I_{m+1} | I_+ | I_m \rangle$$

$$\langle I_{m-1} | I_y | I_m \rangle = \frac{i}{2} \langle I_{m-1} | I_- | I_m \rangle$$

Annotations on the right side of the equations:

- For the first equation: $\langle I_m | I_m \rangle = 1$
- For the second equation: $\langle I_{m-1} | I_{m-1} \rangle = 1$

$$I_y = \frac{-i}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix} \langle I_{11} | I_{-11} \rangle$$

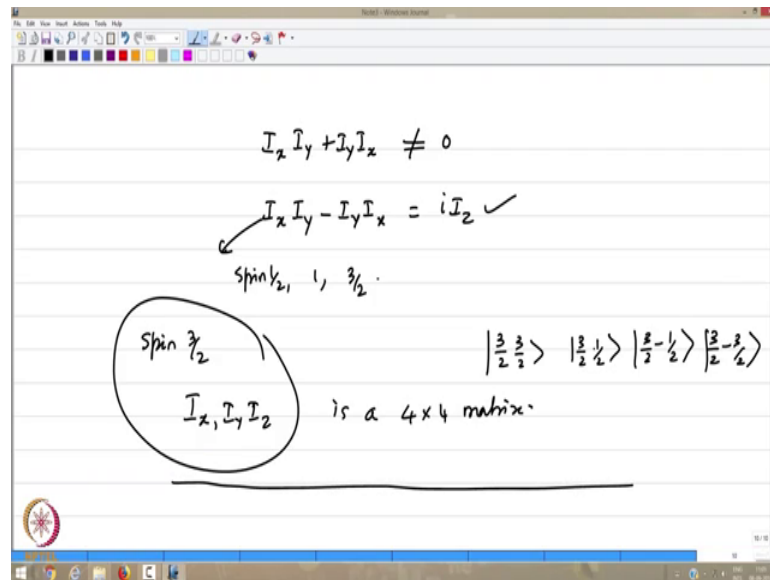

A checkmark is visible next to the matrix.

I y is minus I by 2 I plus minus I minus. Therefore, you can see that I m plus 1 let me write because we know it is going to be only one not the other I y I m will be minus I by 2 I m plus 1 I plus on I m, the minus will bring it down to m minus 1. Therefore, they are orthogonal to each other and I m minus 1 on I y I m will be there is a minus sign here. So, it will be plus I by 2, I m minus 1 I minus on I m, I minus on I m lowers it to one value down and therefore, the normalization property of the states I m I m is one that takes care of and therefore, you can write the same thing as I m minus 1 I m minus 1 that is also what any value of m which is the same on both the (Refer Time: 17:11)

So, given this if we can write the I minus, the I y operator as 1 by or minus I by root 2. Now, let us see this is the first element is 0, because it is diagonal you can write all these things of 0 and to the two of diagonal they are also 0. Therefore, what you have is this element is this element is 1 1 I plus 1 0. So, that corresponds to this type of matrix element 1 1, when m is 0 then you have that and therefore, the corresponding value will be there is a minus I by 2 2 is already taken therefore, this is 1 this would be 1 this will be minus 1 this would be minus 1.

So, this is the representation where you can calculate it based on this formula. There will be some tutorial examples for you to do that, but try to follow this formula namely the first very first one, this formula keep this in mind. These are the properties of spin one operators.

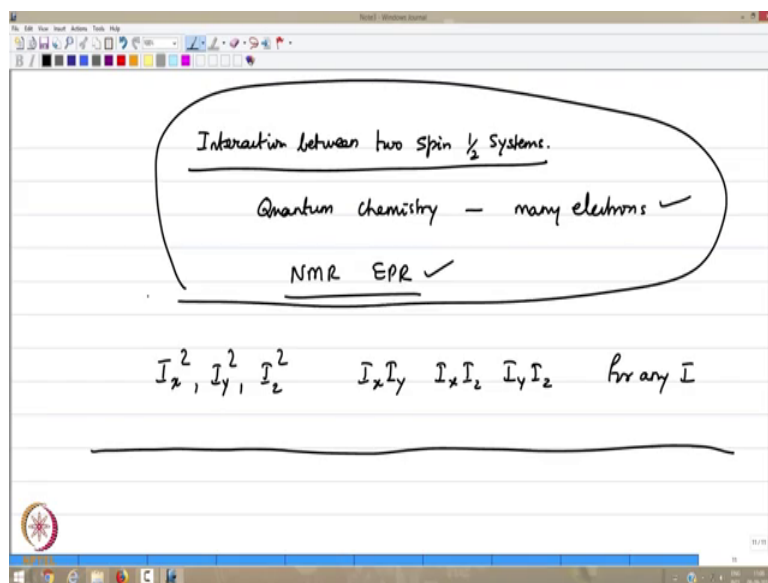

(Refer Slide Time: 18:46)

However, for spin one or any higher spin angular momentum we cannot write $I_x I_y$ plus $I_y I_x$ it is not 0, and for any spin including half the relation is $I_x I_y$ minus $I_y I_x$ is always $i I_z$ always, no matter whether the I corresponds to spin half or spin 1 or 3 halves and so on.

If the system is a spin three half system chlorine nucleus store in 35 nucleus has a nuclear magnetic moment that corresponds to a spin three half system for spin three halves we will have 4 basis functions I_m will be 3 by 2 3 by 2 I minus 1 will be 1 by 2 then you will have 3 by 2 minus 1 by 2 and 3 by 2 minus 3 by 2. So, there are four stage and so, the spin three half representation, the matrix representation for $I_x I_y$ and I_z for a spin three half system is a 4 by 4 matrix, and likewise for any spin I it is a $2 I$ plus 1 by 2 I plus 1 matrix. So, these are properties of these spin half system spin arbitrary spin I systems.

(Refer Slide Time: 20:27)

Now, we will get into an extremely important problem in both spectroscopy and in quantum chemistry namely the interaction between 2 spin half systems. The interaction between 2 spin half systems in quantum chemistry is of course, extremely important because of we deal with electrons, many electron systems. And in nuclei we deal with the nuclear magnetic resonance, electron paramagnetic resonance, NMR spectroscopy, EPR spectroscopy and anywhere where the orbital angular momentum of sorry, anywhere 2 spin half systems interact orbital angular momentum is an integer angular momentum we are only talking about 2 spin half systems.

So, these are all areas where we interactions have to be studied, and since the whole concept requires what is called the spin state representation for a 2 spin system it is like what we was introduced earlier in one of the mathematics lecture notes as the direct product of 2 single component systems and let me do that in the next lecture.

We will stop here in concluding that it is possible for us to write matrix representation for all the operators I_x, I_y, I_z and a host of others namely, $I_x^2, I_y^2, I_z^2, I_x I_y, I_y I_x, I_x I_z, I_z I_x, I_y I_z, I_z I_y$ all these operators for any I . So, we will stop here as the component for single spin systems and in the next lecture let me start looking at to the interaction between the 2 spin half systems from the background of what is meant by a true spin half states, what is meant by the operator representation for those for the 2 spin half states and so on.

So, until then thank you very much.
