**Solving Nonlinear Equations - II**

((Refer Time: 00:18)) series and non and Numerical Methods in Civil Engineering, we are going to continue our discussion on solving non-linear equations.

(Refer Slide Time: 00:25)

**Generalized Iteration Method**

- Both Newton Raphson and Secant methods can be regarded as special instances of a general theory of iteration methods where  $x_{n+1}$  is determined by values of the function  $\phi(x)$  and its derivative at 'm' points i.e.:

$$x_{n+1} = \phi(x_n, x_{n-1}, \dots, x_{n-m})$$

- The function  $\phi$  is known as the iteration function and is obtained by re-writing  $f(x) = 0$  as  $x = \phi(x)$
- When  $m=1$ , we recover  $x_{n+1} = \phi(x_n)$ : a one point iteration

Last time we looked at the Newton Raphson and secant methods for solving one dimensional non-linear equations, this time we want to generalize the concept and talk about some general iteration methods for solving non-linear equations. We are going to first talk about equations with one variables, one dimensional non-linear equations, and then we are going to extend our approach to multidimensional non-linear problems.

So, both Newton Raphson and Secant methods can be regarded as special instances of a general theory of non-linear equation solving, and for instance non-linear iterative method of equation solving. For instance, when we are interested in finding the value of  $x$  at by doing say series of iterations, so we are interested in finding the value of  $x$  at step  $n$  plus 1 provided we know the values of  $x$  at the previous step.

Now, for instance the most general method iterative method  $x_{n+1}$  is a function of the values of  $x$  at  $n$  points, if it is not only the function of the value of  $x$  at  $n$  minus 1 or  $n$

it is actually a function of the values of the function at m point. So, it is a value of x at n, n minus 1 up to n minus n, so this is an m'th order iterative method. So, in that case x n plus 1 is a function of x the value of x at the nth iterate at the n minus 1th iterate and so on up to n minus mth iterate right and that is why it is called a mth it has got m points.

So, that means, that x n plus 1 is a function of the value of x of the value of the function as well as it is derivative at those m points. When m is equal to 1 we recover the one point iteration method basically the Newton Raphson method is a one point iteration method, the secant method is a two point iteration method, because it looks at the function values at n as well as n minus 1. To find the value at n plus 1, we will look at the values at n as well as n minus 1, so the Secant method is a two point iteration method whereas, the Newton Raphson method is a one point iteration method, but we can have in general iteration methods with n points.

(Refer Slide Time: 03:08)

### Generalized Iteration Method

- Suppose that for a one point iteration scheme we have a sequence  $x_{n+1} = \phi(x_n)$  generated with a certain initial value  $x_0$  and let  $\lim_{n \rightarrow \infty} x_n = \alpha$
- Hence,  $\alpha = \lim_{n \rightarrow \infty} x_n = \lim_{n \rightarrow \infty} x_{n+1} = \lim_{n \rightarrow \infty} \phi(x_n) = \phi(\alpha)$  since  $\phi(x)$  is continuous
- Hence the limiting value of the sequence  $\{x_n\}$  is a root of the equation  $\phi(x) = x$

 Thus if we define  $f(x) = \phi(x) - x$ , it is clear that  $\alpha$  is a root of  $f(x) = 0$

Suppose, that for a one point iteration scheme we have a sequence x n plus 1 is equal to phi of x n generated with a certain initial value x 0, and let us suppose that this sequence is convergent, so as we increase the number of iterations as n goes to infinity, x n goes to or known solution which is unknown solution which is alpha. So, we can say alpha is the limit of x n as n goes to infinity, and since the sequence x n is convergent we can as well say that it is the limit where x n plus 1.

It is the limit of  $x_{n+1}$  if  $n$  goes to infinity since the sequence is convergent, it does not matter whether we take  $x_{n+1}$  or  $x_n$  because both of them are going to tend to  $\alpha$ . But, since we once we write it as  $\lim_{n \rightarrow \infty} x_{n+1}$  in the limit  $n$  goes to infinity we can write it as  $\lim_{n \rightarrow \infty} \phi(x_n)$  since our iterative scheme says that  $x_{n+1}$  is equal to  $\phi(x_n)$ .

And since  $\phi(x)$  is continuous we know that as  $n$  goes to infinity  $x_n$  goes to  $\alpha$ , we knew that right, but since this function  $\phi(x)$  is continuous. So, as  $x_n$  goes to  $\alpha$   $\phi(x_n)$  will also go to  $\phi(\alpha)$ , which is not necessarily true if the function  $\phi$  is not continuous, but since the function  $\phi$  is continuous, we know that as  $x_n$  goes to  $\alpha$   $\phi(x_n)$  is going to  $\phi(\alpha)$ . Hence, the limiting value of the sequence  $x_n$  is a root of the equation  $\phi(x) = x$ , so when  $x_n$  reaches  $\alpha$  then we have  $\phi(\alpha) = \alpha$ , we have  $\alpha = \phi(\alpha)$ .

So, what does that mean; the limiting value of this sequence  $x_n$  is a root of the equation  $\phi(x) = x$ , because in that case  $\alpha$  satisfies this equation  $\phi(x) = x$  exactly, so  $\alpha$  is a root of this equation. Thus if we define, if you have a given function  $f(x)$  and from that function, we define  $f(x) = \phi(x) - x$ , so finding the root of  $f(x)$ , finding  $f(x) = 0$ , is equivalent to finding the root of  $\phi(x) = x$ . So, it is clear that if we find the root of  $\phi(x) = x$  with a sequence  $x_n$  tending to  $\alpha$ , we have also found a root of  $f(x) = 0$ . So, we are converting this equation  $f(x) = 0$  to finding the root of  $f(x) = 0$ , to finding the root of this equation  $\phi(x) = x$ .

(Refer Slide Time: 06:14)

**Convergence of Generalized Iteration Method**

Alternatively, we can therefore state that to solve the equation  $f(x) = 0$  we can try rewriting it in the form  $x = \phi(x)$ , which then defines an iteration method  $x_{n+1} = \phi(x_n)$

- A sufficient condition for convergence of the sequence is:

Suppose that  $x = \phi(x)$  has a root  $\alpha$ , and  $\phi'(x)$  exists and satisfies the condition  $|\phi'(x)| \leq m < 1$  in the interval  $J = \{x: |x - \alpha| \leq \rho\}$ .

Then, for all  $x_0 \in J$ : (a)  $x_n \in J, n = 0, 1, 2, \dots$  (b)  $\lim_{n \rightarrow \infty} x_n = \alpha$

$\alpha$  is the only root in  $J$  of  $x = \phi(x)$

Alternatively, we can therefore, state to solve the equation  $f$  of  $x$  equal to 0 we can try rewriting it in the form  $x$  is equal to  $\phi$  of  $x$ , and then which defines an iteration method. Automatically, once you write this you have to naturally get an iteration method like this, and a root of and the once this iteration method converges that is going to be a root of  $f$  of  $x$  is equal to 0.

Next let us look at conditions for convergence, that what when will this sequence  $\phi$  of  $x$  is equal to  $x$  as  $x_{n+1}$  is equal to  $\phi(x_n)$ , when is that sequence going to converge, what are the sufficient conditions for that sequence to converge. Suppose, that  $x$  is equal to  $\phi$  of  $x$  has a root  $\alpha$ , and let us suppose that the derivative  $\phi'$  of  $x$  exists and it satisfies the condition  $|\phi'(x)| \leq m$  which is less than 1.

So, that means, the derivative is bounded the derivative of  $\phi$  of  $x$  is less than some number  $m$ , which is less than 1, in a certain interval neighbor in a neighborhood of my solution. So, in a certain interval neighboring my solution  $\alpha$ , let us suppose that the derivative  $\phi'$  of  $x$  exists and also the derivative  $\phi'$  of  $x$  is bounded, that is its value is less than some specified value in all cases we are saying that specified value  $m$  is less than 1.

So, let us suppose those conditions hold, so  $\phi'$  of  $x$  is less than one in the interval  $J$  where  $J$  is such that any  $x$  belonging to  $J$  its distance from  $\alpha$ , is less than some value  $\rho$ . So, if I take this  $\alpha$  as the center, draw a circle

with radius  $\rho$  all my  $x$  is we are considering all the  $x$ 's which are going to lie within that circle.

And we are saying that for all the  $x$ 's which lie within that circle the derivative  $\phi'$  of  $x$  is bounded, and it is less than some constant  $m$  which is less than 1. Then in that case if we start with some value  $x_0$  within that interval, so we are starting with some value  $x_0$  within that circle with center  $\alpha$  and radius  $\rho$ , then if we keep if we then we start with that value and then put that in our iterative scheme. Let us put that value here, in  $\phi(x_0)$  get  $x_1$ , you can substitute again  $x_1$  here get  $x_2$  and so on and forth.

If you continue our iteration scheme starting with a value in that interval, then we are guaranteed that all our new iterates are going to lie within that interval. So, what it says that is that for all  $x_0$  belonging to  $J$   $x_n$  also is going to belong to  $J$ , for all  $n = 0, 1, 2, \dots$ , so all  $x_1, x_2, x_3$  and so on and so forth. They are all going to lie within that circle with center at  $\alpha$  and radius  $\rho$  and  $I$ , secondly and the limit as  $I$  increase the number of iterations  $x_n$  is going to tend is going to go to  $\alpha$ .

So, it is a very beautiful concept it says that basically I start with a one, if when I am sufficiently close to the root convergence basically means that if I start with any value, which is within a certain neighborhood of the root. And the derivative exists within that in that neighborhood, and the derivative is bounded, then I am bound to get convergence because of my limit my sequence  $x_n$  in the limit  $n$  goes to infinity is going to tend to  $\alpha$ . Number 1, number 2 number 3  $\alpha$  is going to be the only root in  $J$  of  $x$  is equal to  $\phi(x)$ . So, if I satisfy these conditions then these are going to follow.

(Refer Slide Time: 10:30)

**Proof of Convergence Criteria**

To prove (a) suppose that  $x_{n-1} \in J$ . From the definition of the sequence and the fact that the sequence is convergent i.e.  $\phi(\alpha) = \alpha$ , we get  $x_n - \alpha = \phi(x_{n-1}) - \phi(\alpha)$ . Using the mean value theorem,  $x_n - \alpha = \phi(x_{n-1}) - \phi(\alpha) = \phi'(\xi_n)(x_{n-1} - \alpha)$  such that  $\xi_n \in [x_{n-1}, \alpha]$  i.e.  $\xi_n \in J$ .

Hence  $|x_n - \alpha| \leq m|x_{n-1} - \alpha| < m\rho$  (\*)

Thus by induction if  $x_0 \in J$  then  $x_1 \in J$  and so on, which proves (a)

Repeated use of (\*) gives  $|x_n - \alpha| \leq m|x_{n-1} - \alpha| < \dots < m^n|x_0 - \alpha|$

Since  $m < 1$ , this shows that whatever the starting value  $x_0$  as  $n \rightarrow \infty$ ,  $|x_n - \alpha| \rightarrow 0$ . Thus (b) is proved.

How can you prove that well let us suppose we start with a point within j, and let us see if we can prove that if we start with a point within j, then if all those conditions are satisfied then any new iterate is going to lie within j. How can we do that? From the definition of the sequence and the fact that the sequence is convergent that is phi of alpha is equal to alpha.

We can write  $x_n - \alpha = \phi(x_{n-1}) - \phi(\alpha)$  is equal to  $\phi(x_{n-1}) - \phi(\alpha)$ , why because  $x_n$  is equal to  $\phi(x_{n-1})$  according to my iterative scheme and since it is alpha is the root, so alpha is equal to  $\phi(\alpha)$ , so I can write this like this and then I use my mean value theorem. If I use my mean value theorem, I can write  $x_n - \alpha = \phi(x_{n-1}) - \phi(\alpha) = \phi'(\xi_n)(x_{n-1} - \alpha)$  is equal to  $\phi'(\xi_n)(x_{n-1} - \alpha)$  is equal to  $\phi'(\xi_n)(x_{n-1} - \alpha)$  times  $x_{n-1} - \alpha$ .

It is just the mean value theorem this difference is approximated by the derivative evaluated at an intermediate point, times the interval size which is  $x_{n-1} - \alpha$ . This is going to be true such if there is a  $\xi_n$  which belongs to j, belongs to this interval,  $\xi_n$  is going to belong to j because  $x_{n-1}$  belongs to  $x_{n-1} - \alpha$ , and I have already assumed that  $x_{n-1}$  belongs to j. So, it since  $\xi_n$  lies in the in that interval it; obviously, means that  $\xi_n$  also belongs to j, and then if I take mod of

both sides I have  $x_{n+1} - \alpha$  is less than or equal to  $m$  times  $|x_n - \alpha|$ . Why is that  $m$ ?

(Refer Slide Time: 12:43)

### Convergence of Generalized Iteration Method

Alternatively, we can therefore state that to solve the equation  $f(x) = 0$  we can try rewriting it in the form  $x = \phi(x)$ , which then defines an iteration method  $x_{n+1} = \phi(x_n)$

- A sufficient condition for convergence of the sequence is:

Suppose that  $x = \phi(x)$  has a root  $\alpha$ , and  $\phi'(x)$  exists and satisfies the condition  $|\phi'(x)| \leq m < 1$  in the interval  $J = \{x : |x - \alpha| \leq \rho\}$ . Then, for all  $x_0 \in J$ : (a)  $x_n \in J, n = 0, 1, 2, \dots$  (b)  $\lim_{n \rightarrow \infty} x_n = \alpha$

$\alpha$  is the only root in  $J$  of  $x = \phi(x)$

Because, I know that anywhere in that interval  $J$  right my derivative is bounded, if my derivative is going to be less than  $m$ , that is that was our assumption that  $\phi'$  exists and  $|\phi'| \leq m < 1$ .

(Refer Slide Time: 12:52)

### Proof of Convergence Criteria

To prove (a) suppose that  $x_{n-1} \in J$ . From the definition of the sequence and the fact that the sequence is convergent i.e.  $\phi(\alpha) = \alpha$ , we get  $x_n - \alpha = \phi(x_{n-1}) - \phi(\alpha)$ . Using the mean value theorem,  $x_n - \alpha = \phi(x_{n-1}) - \phi(\alpha) = \phi'(\xi_n)(x_{n-1} - \alpha)$  such that  $\xi_n \in [x_{n-1}, \alpha]$  i.e.  $\xi_n \in J$ .

Hence  $|x_n - \alpha| \leq m|x_{n-1} - \alpha| < m\rho$  (\*)

Thus by induction if  $x_0 \in J$  then  $x_1 \in J$  and so on, which proves (a)

Repeated use of (\*) gives  $|x_n - \alpha| \leq m|x_{n-1} - \alpha| < \dots < m^n|x_0 - \alpha|$

Since  $m < 1$ , this shows that whatever the starting value  $x_0$  as  $n \rightarrow \infty$ ,  $|x_n - \alpha| \rightarrow 0$ . Thus (b) is proved.

So, that means, that this thing this  $\phi'$  has to be less than  $m$ , so we have  $m$  here, and since we have taken mod of both sides we have mod of  $x_{n+1} - \alpha$

alpha and since  $x_{n-1}$  belongs to  $J$  this thing must be less than  $\rho$ . So,  $\text{mod of } x_n - \alpha$  is less than  $m\rho$  what does that mean; that means, that  $x_n$  also lies within  $J$ , because  $x_n - \alpha$  is less than  $m\rho$  and what is my  $J$ .

$J$  is such that  $x - \alpha$  is less than or equal to  $\rho$ , and since  $x_n - \alpha$  is less than or equal to  $m$  times  $\rho$  some fraction  $m$  is less than one. So, since this is less than this; obviously, means that  $\text{mod of } x_n - \alpha$  must be less than  $m\rho$ , so  $x_n$  must be lying within that circle which I drew with center  $\alpha$  and radius  $\rho$ . Thus by induction if  $x_0$  belongs to  $J$   $x_1$  is going to be, so we started with any arbitrary  $x_n - x_{n-1}$  which belong to  $J$ .

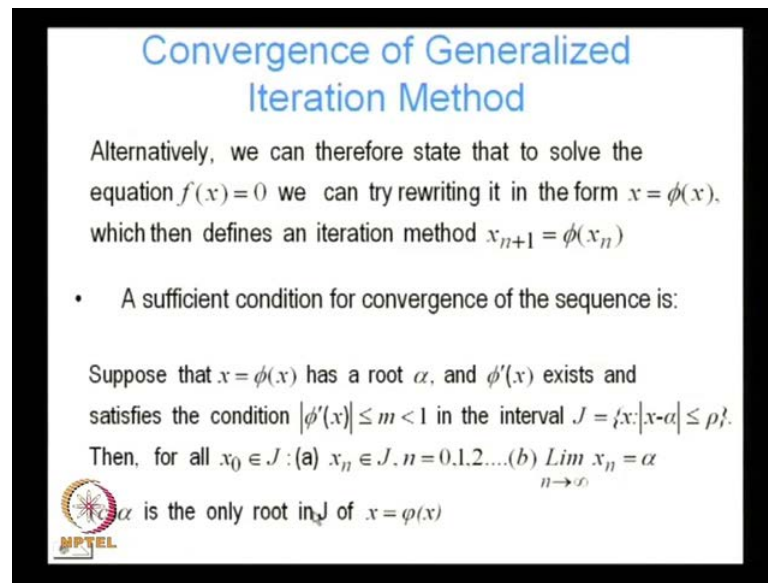

So, if I start with  $x_0$  I knew that  $x_1$  is going to belong to  $J$  since  $x_0$ , and then if  $x_1$  belongs to  $J$  same argument  $x_2$  is going to belong to  $J$  and so on and so forth. So, all my iterates are going to lie within that circle, so that is the first requirement of convergence, so when I am within at within a sufficiently close neighborhood of my root, and then if I satisfy those conditions on the derivative then in that case my all my iterates will belong within that circle.

So, repeated use of this expression repeated use of this expression this is my  $x_n - \alpha$  is lesser than or equal to this I already got,  $x_n - \alpha$  is lesser than or equal to  $m$  times  $\text{mod of } x_{n-1} - \alpha$ . Then if I use the same procedure and this I can show that  $\text{mod of } x_n - \alpha$  is going to be less than  $n$  times  $\text{mod of } x_{n-2} - \alpha$  and so on and so forth.

So, eventually I can show that this is going to be less than  $m^n$  times  $\text{mod of } x_0 - \alpha$ , and remember  $x_0 - \alpha$  is within that circle with center  $\alpha$  and radius  $\rho$  so; that means, that as I keep on iterating, I am going to get  $x_n - \alpha$  is going to less than  $m^n$  times  $\rho$  and remember  $m$  is less than 1. So,  $m^n$  is going to become smaller and smaller as  $n$  increases, so eventually my  $x_n$  is going to converge, so since  $m$  is less than 1. So, this shows that whatever will be the starting value  $x_0$  as  $n$  goes to infinity  $x_n - \alpha$  is going to 0.

(Refer Slide Time: 16:06)

**Convergence of Generalized Iteration Method**

Alternatively, we can therefore state that to solve the equation  $f(x) = 0$  we can try rewriting it in the form  $x = \phi(x)$ , which then defines an iteration method  $x_{n+1} = \phi(x_n)$

- A sufficient condition for convergence of the sequence is:

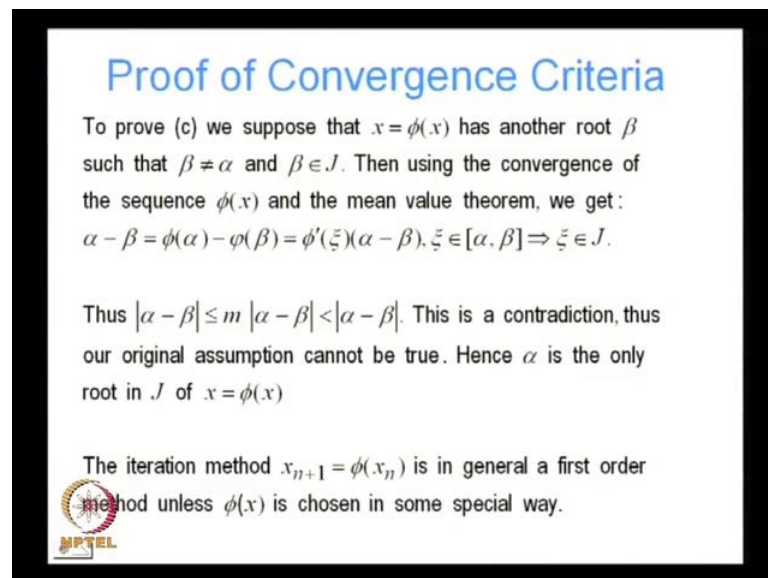

Suppose that  $x = \phi(x)$  has a root  $\alpha$ , and  $\phi'(x)$  exists and satisfies the condition  $|\phi'(x)| \leq m < 1$  in the interval  $J = \{x: |x - \alpha| \leq \rho\}$ . Then, for all  $x_0 \in J$ : (a)  $x_n \in J, n = 0, 1, 2, \dots$  (b)  $\lim_{n \rightarrow \infty} x_n = \alpha$

$\alpha$  is the only root in  $J$  of  $x = \phi(x)$

Thus we have prove the second part which was that this is going to converge, that this sequence  $x_n$  is going to converges and goes to infinity.

(Refer Slide Time: 16:17)

**Proof of Convergence Criteria**

To prove (c) we suppose that  $x = \phi(x)$  has another root  $\beta$  such that  $\beta \neq \alpha$  and  $\beta \in J$ . Then using the convergence of the sequence  $\phi(x)$  and the mean value theorem, we get:

$$\alpha - \beta = \phi(\alpha) - \phi(\beta) = \phi'(\xi)(\alpha - \beta), \xi \in [\alpha, \beta] \Rightarrow \xi \in J.$$

Thus  $|\alpha - \beta| \leq m |\alpha - \beta| < |\alpha - \beta|$ . This is a contradiction, thus our original assumption cannot be true. Hence  $\alpha$  is the only root in  $J$  of  $x = \phi(x)$

The iteration method  $x_{n+1} = \phi(x_n)$  is in general a first order method unless  $\phi(x)$  is chosen in some special way.

And finally, to prove c we said that in that case alpha is going to be the only root in that interval in that neighborhood j, so if you let us see what happens if case in case there is another root, is that possible to proof prove see. This suppose that x is equal to phi x has another root b within that interval j such that b is not equal to alpha; that means, the b also satisfies the phi of b equal to b.

It satisfies that equation, sorry not  $\phi(\beta) = \beta$ , but  $\beta$  is not equal to  $\alpha$ . Then using the convergence of the sequence  $\phi^n(x)$  and the mean value theorem we get  $\alpha - \beta = \phi(\alpha) - \phi(\beta)$ , because both  $\alpha$  and  $\beta$  are roots of this,  $\phi(\alpha) - \phi(\beta)$ , then I again use my mean value theorem. So, this I can write is  $\phi'(\psi)(\alpha - \beta)$ , so long as  $\psi$  belongs to  $J$ , which means that  $\psi$  belongs to  $J$  since both  $\alpha$  and  $\beta$  belong to  $J$ .

So, I will this lies in that interval function is continuous, so  $\psi$  must belong to  $J$ . So, thus if then again we take the mod of both sides mod of  $\alpha - \beta$  is lesser than or equal to mod of  $\phi'(\psi)$  which is  $m$  which has to be less than  $m$ , which is the condition we said times mod of  $\alpha - \beta$  which is less than mod of  $\alpha - \beta$ .

So,  $m$  since  $m$  is less than 1, this has to be less than mod of  $\alpha - \beta$  which is not possible,  $\alpha - \beta$  cannot be less than  $\alpha - \beta$ , which is impossible this is a contradiction. Thus the original assumption that  $\phi^n(x)$  has another root  $\beta$  in that interval is false, and hence  $\alpha$  is the only root of  $J$  only root in  $J$  of  $x$  is equal to  $\phi^n(x)$ . The  $J$  iteration method  $x_{n+1} = \phi(x_n)$  is in general, a first order method unless  $\phi^n(x)$  is chosen in some special way, what do I mean by a first order method; that means, that the order of convergence is normally first order.

Unless there are some special conditions of on  $\phi^n(x)$  we know that Newton's Newton Raphson is a second order method, while the secant method we found was not clearly a first order method it might had a convergence value, it had rather somewhere between 1 and 2 something like 1.6 something. So, in case we choose, so in case we have to improve the order of convergence of that method, in that case the function  $\phi^n(x)$  must satisfy certain additional properties. what are those additional properties? And how do those additional properties? Influence the order of convergence of the function, so that is what we want to talk about next.

(Refer Slide Time: 19:24)

### Order of Convergence of Generalized Iteration Method

Let us assume  $\phi(x)$  is  $p$  times differentiable in a nbd. of  $\alpha$  where  $\alpha = \phi(\alpha)$ . Let us also assume that all the derivatives of  $\phi(x)$  upto order  $p-1$  are 0 at  $\alpha$  i.e.  $\phi^{(j)}(\alpha) = 0, j = 1, 2, \dots, p-1$ , while  $\phi^{(p)}(\alpha) \neq 0$ . Using Taylor's theorem we have, for  $\xi_n \in [x_n, \alpha]$ :

$$x_{n+1} = \phi(x_n) = \phi(\alpha + x_n - \alpha) = \phi(\alpha) + \frac{\phi^{(p)}(\xi_n)}{p!} (x_n - \alpha)^p$$

But  $\phi(\alpha) = \alpha$ . Hence  $(x_{n+1} - \alpha) = \frac{\phi^{(p)}(\xi_n)}{p!} (x_n - \alpha)^p$ . Thus,

$$\left| \frac{\phi^{(p)}(\xi_n)}{p!} \right| \leq \frac{|\phi^{(p)}(\xi_n)|}{p!} |\varepsilon_n|^p. \text{ In the limit } x_n \rightarrow \alpha, \frac{|\varepsilon_{n+1}|}{|\varepsilon_n|^p} = \frac{|\phi^{(p)}(\alpha)|}{p!} \neq 0$$

So, let us assume that phi of x is p times differentiable in a neighborhood of alpha, so if I take p derivatives all those derivatives exist, so p derivatives exist in a neighborhood of alpha, where alpha is equal to phi of alpha, alpha is a root of that equation. So, let us also assume that all the derivatives of phi of x up to order p minus 1 are 0 at alpha, so let us this is the crucial part this is the additional assumption that we have to make.

We are making the assumption that all the derivatives of phi up to the order p minus 1 are 0 at the root alpha right and the derivatives of order p is not equal to 0, so if under those conditions we can show that the order of convergence can be higher, and how high will it be well let us take a look. So, in that case since all the derivatives up to order p minus 1 are 0 if we use Taylor's series expansion for  $x_{n+1}$  equal to phi of  $x_n$  this is from an iteration algorithm,  $x_{n+1}$  is equal to phi of  $x_n$  it I can write this as phi of alpha plus  $x_n$  minus alpha.

And then I do a Taylor's series expansion about alpha, so if I do a Taylor series expansion about alpha what do I get, I get phi of alpha plus in the normal course of events. I would have first derivative phi prime evaluated at alpha times  $x_n$  minus alpha plus the second term would be phi double prime evaluated at alpha times  $x_n$  minus alpha square by factorial of two and so on and so forth.

But, remember what is our condition our condition is that all derivatives up to order p minus 1 are 0 at alpha, so all the p minus 1 derivatives, they vanish, because that they are

all 0 by assumption. And then we are left with only the  $p$ th derivative and we can evaluate the 2<sup>nd</sup>  $p$ th with which this as the remainder term in the Taylor's series, we can then cut off our Taylor's series at that point.

If we can write this as  $\phi$ ,  $p$ th derivative of  $\phi$  evaluated at  $\psi_n$  divided by factorial of  $p$  times  $x_n - \alpha$  to the power  $p$ , where  $\psi_n$  belongs to this interval. Where,  $\psi_n$  belongs to this interval, but  $\phi$  of  $\alpha$  is equal to  $\alpha$  since  $\alpha$  is a root of this, this equation  $\phi(x) = x$ , so this and this, so this I can replace by  $\alpha$ . So, I get  $x_n - \alpha$  by bringing  $\phi$  of  $\alpha$  to the left hand side I have  $x_n - \alpha$ , and this is  $\phi$  to the power  $p$   $\psi_n$  by factorial  $p$  times  $x_n - \alpha$  to the power  $p$ , so what does this remind you.

So, here on the left hand side we have  $x$  and  $x_n - \alpha$ , which is nothing but the error at the  $n + 1$ th iteration, because this is  $\epsilon_{n+1}$  it gives me it gives me how much if I take the mod of this, it gives me by how much the  $n + 1$ th iterate differs from the root. And that is my error at the  $n + 1$ th iteration, well on the right hand side I have this term, what is this term it is the error at the  $n$ th iterate  $x_n - \alpha$  is equal to  $\epsilon_n$ .

So, now, I have a relation which says that the error the mod of the error at the  $n + 1$ th iteration is less than this term multiplied by the mod of the error of the  $n$ th iteration to the power  $p$ , so this is we call this is we emphasize this. When, we talk about Newton's method and the Secant method that if you have to establish the order of convergence you have to be able to write the  $n + 1$ th error in terms of the  $n$ th error.

So, we have just done that and in the limit as  $x_n$  goes to  $\alpha$  we have  $\epsilon_{n+1}$  to the divided by  $\epsilon_n$  mod to the power  $p$   $\phi^{(p)}(\alpha)$  because now  $x_n$  is going to  $\alpha$ , so  $\psi_n$  must be  $\psi_n$  has to tend to  $\alpha$ , because everything is converging to  $\alpha$ . So, we have this thing which is a constant and which is not equal to 0 why is that not equal to 0, because of I requirement write here which says that  $\phi'(\alpha)$  is not equal to 0. So, this term is a constant this is not equal to 0 and we have a error at  $\epsilon_{n+1}$  is equal to this constant, times  $p$  times the error of  $\epsilon_n$ . So, just by looking at this we can say lets think of Newton Raphson, Newton Raphson we know that  $p$  is equal to 2, that is the order of convergence is equal to 2.

So, what does that mean what does that require in terms of this requirement, so for Newton Raphson to be quadratically convergent number 1 the function must have first derivative, which is equal to 0 at alpha. And the second derivative p is equal to second, so the first derivative must be 0 at alpha and the second derivative must not be 0 at alpha, so that is the requirement under which Newton Raphson is going to give me second order convergence.

(Refer Slide Time: 25:41)

**Specializing to Newton Raphson**

Thus the iteration method  $x_{n+1} = \phi(x_n)$  is of order  $p$  for the root  $\alpha$  if  $\phi^{(j)}(\alpha) = 0, j = 1, 2, \dots, p-1$  and  $\phi^{(p)}(\alpha) \neq 0$ .

Recall that for Newton-Raphson  $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$ .

We get it in the form  $x_{n+1} = \phi(x_n)$  if we write  $\phi(x_n) = x_n - \frac{f(x_n)}{f'(x_n)}$ .

Hence  $\phi(x) = x - \frac{f(x)}{f'(x)}$  and  $\phi'(x) = \frac{f(x)f''(x)}{[f'(x)]^2}$ .

If  $\alpha$  is a simple root of  $f(x)$ , then  $f(\alpha) = 0, f'(\alpha) \neq 0$ .

Hence  $\phi'(\alpha) = 0$ .

Thus the iteration method  $x_{n+1} = \phi(x_n)$  is of order  $p$  for the root  $\alpha$  if  $\phi^{(j)}(\alpha) = 0$  for  $j = 1, 2, \dots, p-1$  and  $\phi^{(p)}(\alpha) \neq 0$ , at  $\alpha$ . Let us recall that for Newton Raphson, we can write  $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$ .

So, in that case what is our  $\phi$  our  $\phi$  is nothing but this function on the left hand side, so we can write  $\phi(x_n) = x_n - \frac{f(x_n)}{f'(x_n)}$ . Hence,  $\phi(x)$  is nothing but this and  $\phi'(x)$ , if I take the derivative of this, this is equal to this. And let us recall again what is our definition of a simple root of  $f$  of  $x$ ,  $\alpha$  is a simple root of  $f$  of  $x$  and  $f(\alpha) = 0$  and  $f'(\alpha) \neq 0$ .

Since,  $f'(\alpha) \neq 0$  and  $f(\alpha) = 0$ , what can we say about  $\phi'(\alpha)$   $\phi'(\alpha) = 0$ . Why?  $\phi'(\alpha)$  is equal to  $\frac{f(\alpha)f''(\alpha)}{[f'(\alpha)]^2}$  by definition is 0, because  $\alpha$  is a root of that and  $\phi$

prime  $f'$  of  $\alpha$  is not equal to 0. So, this is never going to blow up, this is going to be bounded, this is going to be bounded, but on the top we have so; that means, that  $\phi'$  of  $\alpha$  must be equal to 0. And if  $\phi'$  of  $\alpha$  is equal to 0 and  $\phi''$  of  $\alpha$  is not equal to 0, then we are going to have quadratic convergence of Newton Raphson.

(Refer Slide Time: 27:41)

**Higher order of convergence**

Thus we are guaranteed that the Newton Raphson method is at least of second order for simple roots. If  $f''(\alpha) = 0$ , then  $\phi''(\alpha) = 0$  and Newton's method is at least of third order.

- There are many general methods for constructing iteration schemes with higher order of convergence.
- It can be shown that a one point iterative scheme of order  $p$  requires computation of  $p$  quantities:  $f(x_n), f'(x_n), \dots, f^{(p-1)}(x_n)$

Thus it is clear that the higher order of convergence comes at

 NIT Calicut.

Thus we are guaranteed that the Newton Raphson is at least quadratically convergent for simple roots, if in addition  $f''$  of  $\alpha$  is equal to 0, then we can show that  $\phi''$  of  $\alpha$  is equal to 0. In that case the Newton Raphson convergence is going to be at least of third order, because the second derivative is 0, third derivative may or may not be 0.

If it is not 0 then it has to be at least third order, if it is 0 then we are going to have even higher order convergence. So, in that case if  $\phi''$  of  $\alpha$  is equal to 0 then the Newton Raphson method is also going to be convergent at least up to third order. There are many general methods for construction, so this we can see that we can make the Newton Raphson scheme. We can make the incase this condition is satisfied Newton Raphson is going to be third order convergent, but that is incase that is satisfied, but by construction the Newton Raphson method is second order convergent, because we saw that whatever be the function  $f$  of  $x$ .

(Refer Slide Time: 28:53)

**Specializing to Newton Raphson**

Thus the iteration method  $x_{n+1} = \phi(x_n)$  is of order  $p$  for the root  $\alpha$  if  $\phi^{(j)}(\alpha) = 0, j = 1, 2, \dots, p-1$  and  $\phi^{(p)}(\alpha) \neq 0$ .

Recall that for Newton-Raphson  $x_{n+1} = x_n - \frac{f(x_n)}{f'(x_n)}$ .

We get it in the form  $x_{n+1} = \phi(x_n)$  if we write  $\phi(x_n) = x_n - \frac{f(x_n)}{f'(x_n)}$ .

Hence  $\phi(x) = x - \frac{f(x)}{f'(x)}$  and  $\phi'(x) = \frac{f(x)f''(x)}{[f'(x)]^2}$ .

If  $\alpha$  is a simple root of  $f(x)$ , then  $f(\alpha) = 0, f'(\alpha) \neq 0$ .

Hence  $\phi'(\alpha) = 0$ .

So, long as this condition is satisfied, which is a prerequisite,  $f'$  prime of  $\alpha$  is not equal to 0 right in that case the Newton Raphson method is going to be second order convergent, but in case in addition in addition if we have  $f''$  double prime equal to 0 in that case we can have higher order convergence of the Newton Raphson method.

(Refer Slide Time: 29:15)

**Higher order of convergence**

Thus we are guaranteed that the NewtonRaphson method is at least of second order for simple roots. If  $f''(\alpha) = 0$ , then  $\phi''(\alpha) = 0$  and Newton's method is at least of third order.

- There are many general methods for constructing iteration schemes with higher order of convergence.
- It can be shown that a one point iterative scheme of order  $p$  requires computation of  $p$  quantities:  $f(x_n), f'(x_n), \dots, f^{(p-1)}(x_n)$

Thus it is clear that the higher order of convergence comes at a cost.

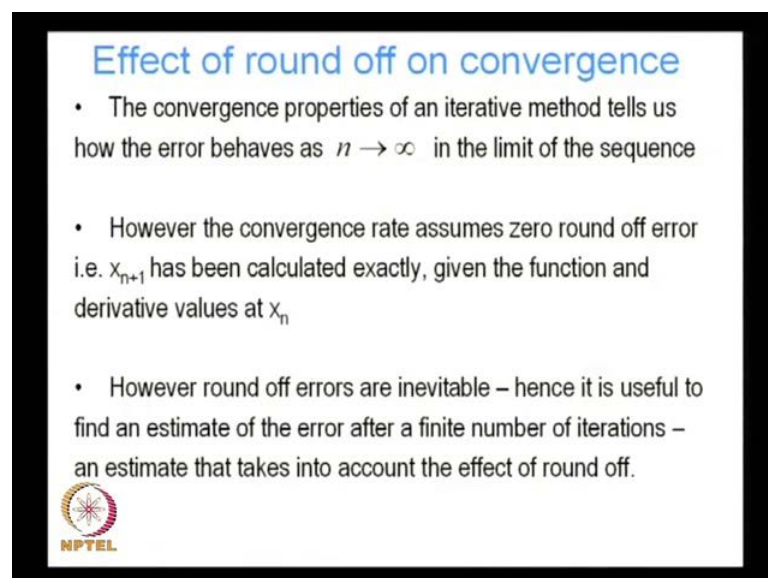

There are many general methods for constructing iteration schemes with higher order of convergence, it can be shown that for a one point iterative scheme of order  $p$  requires computation of  $p$  quantities basically we need to compute  $p$  quantities. what are those

quantities? The function and its first  $p - 1$  derivatives therefore, as you can see to improve the order of convergence there is a cost, because each time you take the you need to calculate a derivative it is expensive.

So, if you can improve the order of convergence, you can have as many high order of convergence as you like, but ultimately it becomes it does not it is no longer economical computationally economical, but the cost of taking all these derivatives. You can say you can lower the order of convergence, so by lowering the order of convergence what we are going to get we are going to converging fewer number of iterations.

But, the cost of taking all those derivatives and converging in a fewer number of iterations is going to be more than the cost of calculating less derivatives there the order of convergence is less, but the number of iterations is more. So, if you take a lower order method you need more iterations, but you need to compute only a limited number of derivatives, so it all depends on a tradeoff. So, it turns out that if you have to compute more and more derivatives then the cost of reducing the number of iterations is much, much is offset by the cost of calculating the derivatives. So, people will prefer to take a lower comparatively lower order method do more number of iterations and that is come computationally more efficient.

(Refer Slide Time: 31:19)

**Effect of round off on convergence**

- The convergence properties of an iterative method tells us how the error behaves as  $n \rightarrow \infty$  in the limit of the sequence
- However the convergence rate assumes zero round off error i.e.  $x_{n+1}$  has been calculated exactly, given the function and derivative values at  $x_n$
- However round off errors are inevitable – hence it is useful to find an estimate of the error after a finite number of iterations – an estimate that takes into account the effect of round off.

So, the convergence properties of an iterative method tells us, how the error behaves as  $n$  goes to infinity in the limit of the sequence; however, in all our derivations, so far we

have assumed that there is zero round off error. So, when we calculate phi of x n plus 1 from phi of x n, we are assuming that there is no round off error, but in reality. There is going to be; obviously, going to be round off error, because whenever we compute phi of x n we are not going to compute phi of x n exactly we are only going to compute it up to our machine accuracy.

Because, we are using finite precision arithmetic I compute that has that many limited floating point numbers, it can store for my mantissa. So, I have to I am bound to get some round off errors and how are those round off errors going to affect my convergence, so that is that also is interesting. Hence, round off errors are inevitable, hence it is useful to find an estimate of the error after finite number iterations an estimate that takes into account the effect of the round off. So, up till now all convergence loss, convergence relationships they have all assumed that round off non existing.

(Refer Slide Time: 32:51)

### Effect of round off on convergence

Let us denote by  $\bar{x}_1, \bar{x}_2, \dots, \bar{x}_n$  the sequence of approximations and let the error at each stage due to round off be denoted by  $\delta_n$ . Then  $\bar{x}_{n+1} = \phi(\bar{x}_n) + \delta_n, n = 0, 1, \dots$ . Subtracting the converged sequence  $\alpha = \phi(\alpha)$  from both sides, we get:

$$\bar{x}_{n+1} - \alpha = \phi(\bar{x}_n) - \alpha + \delta_n = \phi'(\xi_n)(\bar{x}_n - \alpha) + \delta_n, \xi_n \in [\bar{x}_n, \alpha]$$

Subtracting  $\phi'(\xi_n)\bar{x}_{n+1}$  from both sides and rearranging terms, we get:  $[1 - \phi'(\xi_n)](\bar{x}_{n+1} - \alpha) = \phi'(\xi_n)(\bar{x}_n - \bar{x}_{n+1}) + \delta_n$

Assuming bounds on both derivative and error i.e.  $|\phi'(\xi_n)| \leq m < 1$  and  $|\delta_n| < \delta$ , we get:  $|\bar{x}_{n+1} - \alpha| < \frac{m|\bar{x}_{n+1} - \bar{x}_n|}{(1-m)} + \frac{\delta}{(1-m)}$

So, let us denote by  $x_1, \bar{x}_1, \bar{x}_2, \dots, \bar{x}_n$  the sequence of why we are using a bar and term, because we want to denote them as the real sequence of approximations meaning they have round off in them. While,  $x_1, x_2, x_3, \dots, x_n$  did not have any round off, a sort of a ideal iterative values, which assume that there is no round off.

Let us now consider  $\bar{x}_1, \bar{x}_2, \dots, \bar{x}_n$ , where there is round off, and let the error at each stage due to round off will be denoted by delta I, then we can write  $\bar{x}_{n+1}$  is equal to phi of  $\bar{x}_n$  plus some delta n, because there is this round off, so delta n is my

round off for  $n$  is equal to  $0.1$  and so on and so forth. So, this is going to be true at every stage in our iteration, so subtracting the converged sequence  $\alpha$  is equal to  $\phi$  of  $\alpha$  from both sides, so we subtract  $\alpha$  equal to  $\phi$  of  $\alpha$  from both sides.

So, we have  $\bar{x}_{n+1} - \alpha$  is equal to  $\phi(\bar{x}_n - \alpha) + \delta_n$ , again I use my mean value theorem. So,  $\phi(\bar{x}_n - \alpha)$  I am going to write it as because  $\alpha$  is equal to  $\phi(\alpha)$ , so  $\phi(\bar{x}_n - \alpha) - \phi(\alpha)$  I am going to write as  $\phi'(\psi_n) \times (\bar{x}_n - \alpha)$ , where  $\psi_n$  belongs to  $\bar{x}_n$  and  $\alpha$ . I can only do that because  $\alpha$  is equal to  $\phi(\alpha)$ , I can use my mean value theorem here.

Then if I subtract  $\phi'(\psi_n) \times (\bar{x}_n - \alpha)$  from both sides, and rearrange terms I am going to get something like this, which is basically  $\bar{x}_{n+1} - \alpha$  is equal to  $(1 - \phi'(\psi_n)) \times (\bar{x}_n - \alpha) + \delta_n$ . So, let us assume bounds on both the derivative and the error, so let us assume that the derivative is bounded, that  $\phi'(\psi_n)$  is lesser than or equal to  $m$  less than one which is what we assumed earlier remember.

So, that is what we assume earlier and let us assume that a round off error is also bound which is true, because round off error is bounded by the we have seen that into a detail earlier in the in the beginning of the course round off error is bounded by things like machine precision and things like that right. So, the round off error is also bounded, and let us suppose that bound is  $\delta$  we therefore, get by taking mod of both sides mod of  $\bar{x}_{n+1} - \alpha$ .

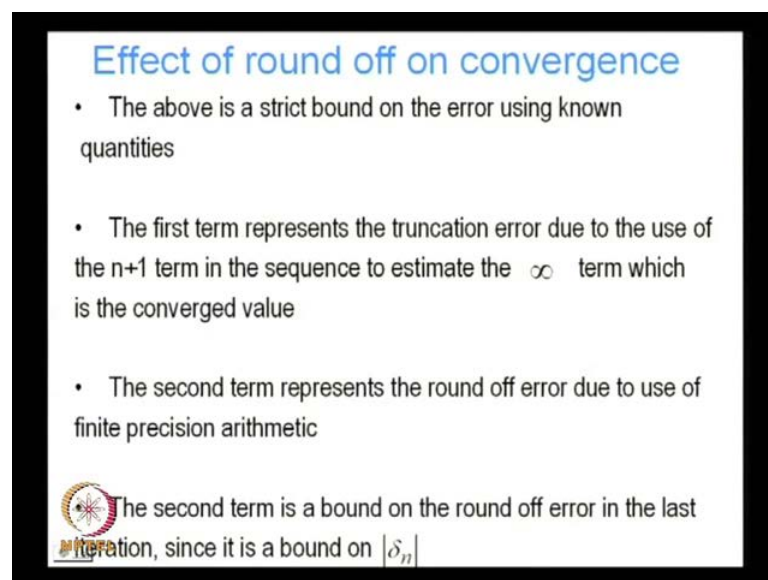

And then if you take mod of this what is this going to be, this is going to be  $(1 - m)^{n+1} \times (\bar{x}_0 - \alpha) + \delta \times \frac{1 - (1 - m)^{n+1}}{m}$ , because mod of  $\phi'(\psi_n)$  is less than equal to  $m$ . Then if I divide both sides by  $(1 - m)^{n+1}$  this has also got bound  $m$ , so for  $n$  times mod of  $\bar{x}_{n+1} - \alpha$  divided by  $(1 - m)^{n+1}$  plus  $\delta \times \frac{1 - (1 - m)^{n+1}}{m}$ . So, this gives me a bound on my  $\bar{x}_{n+1} - \alpha$ , this gives a bound on my error at the  $n+1$ th iteration that takes into account the effect of round off, because of this term.

So, this says that at any stage in my iteration at stage  $n+1$  for instance, my error is going to be bounded by these values right and this, these are two parts you can see, so the first part is what is known as the truncation error. In any numerical method in any this we talked about also right in the first class in any numerical method, there are two

there are bound to be two types of errors any numerical algorithm for solving a problem, there are going to be two types of errors.

One type of error is going to be the truncation error, the second type of error is going to be the round off error. Why do we have the truncation error? The truncation error is because when you are approximating an infinite sequence by a finite number the terms, in this case we are approximating alpha which is actually the limit of the sequence  $\phi$  of  $x_n$  it is the limit. When  $n$  goes to infinity by the term at the after the  $n+1$ th iteration, so an approximating the infinite term on the sequence by the  $n+1$ th term, because of that there is an error and that error is my truncation error, and this error is my round off error.

(Refer Slide Time: 38:06)

**Effect of round off on convergence**

- The above is a strict bound on the error using known quantities
- The first term represents the truncation error due to the use of the  $n+1$  term in the sequence to estimate the  $\infty$  term which is the converged value
- The second term represents the round off error due to use of finite precision arithmetic

The second term is a bound on the round off error in the last iteration, since it is a bound on  $|\delta_n|$

So, the above is a strip bound on the error using known quantities, the first term represents the truncation error due to the use of the  $n+1$ th term in the sequence to estimate the infinite term, which is my converged value alpha. So, that is my truncation error the second term represents the round off error due to user finite precision arithmetic any prime, I do not have infinite precision, finite precision arithmetic that is going to give me that error. The second term is a bound on the round off error, this is very important term the second term is a bound on the round off error in the last iteration.

(Refer Slide Time: 38:46)

**Effect of round off on convergence**

Let us denote by  $\bar{x}_1, \bar{x}_2, \dots, \bar{x}_n$  the sequence of approximations and let the error at each stage due to round off be denoted by  $\delta_i$ . Then  $\bar{x}_{n+1} = \phi(\bar{x}_n) + \delta_n, n = 0, 1, \dots$ . Subtracting the converged sequence  $\alpha = \phi(\alpha)$  from both sides, we get:

$$\bar{x}_{n+1} - \alpha = \phi(\bar{x}_n) - \alpha + \delta_n = \phi'(\xi_n)(\bar{x}_n - \alpha) + \delta_n, \xi_n \in [\bar{x}_n, \alpha]$$

Subtracting  $\phi'(\xi_n)\bar{x}_{n+1}$  from both sides and rearranging terms, we get:  $[1 - \phi'(\xi_n)](\bar{x}_{n+1} - \alpha) = \phi'(\xi_n)(\bar{x}_n - \bar{x}_{n+1}) + \delta_n$

Assuming bounds on both derivative and error i.e.  $|\phi'(\xi_n)| \leq m < 1$  and  $|\delta_n| \leq \delta$ , we get:  $|\bar{x}_{n+1} - \alpha| < \frac{m|\bar{x}_n - \bar{x}_{n+1}|}{(1-m)} + \frac{\delta}{(1-m)}$

Since, it is a bound on delta n look at this delta is delta is a bound on mod of delta n, delta is not a bound on delta n minus 1 or whatever any time in that it is a bound on the error in the in the round off error in the last iteration right which is very, very crucial. Let us see why?

(Refer Slide Time: 39:14)

**Effect of round off on convergence**

- It is important to note that the second term says nothing about the round off errors during the previous iterations
- This means that the round off error in the solution depends only on the round off error in the last iteration
- This is a very important result, since it means that that the round off errors in the previous iterations are self correcting.
- It also means that it is not necessary to compute with full accuracy in the first few iterations.

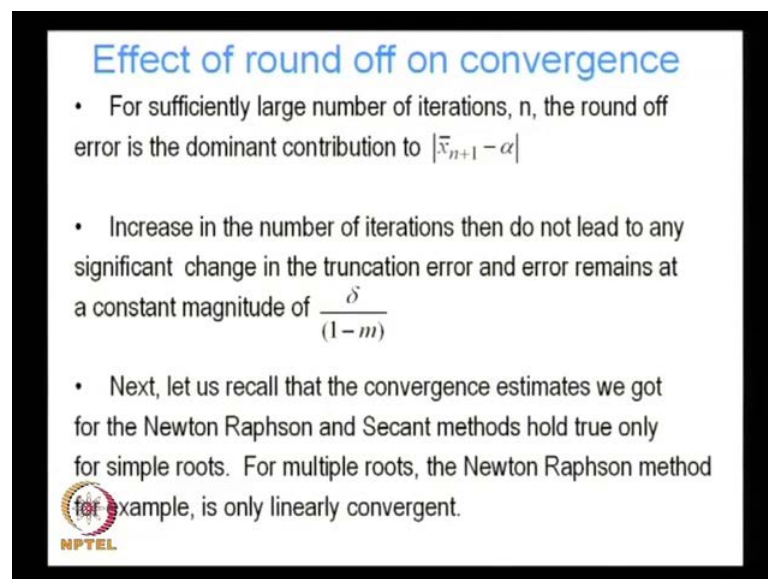

It is important to note that the second term says nothing about the round off errors during the previous iterations, it deals with the round off error in the nth iteration. This means that the round off error in the solution is going to depend on the round off error only in

the last iteration, which is very, very important, because what does that mean; my round off errors in the previous iterations are not contributing to my final round off error. Why?

Because, those round off errors are cancelling each other out, it is very otherwise you can see that if they do not cancel each other out then my error is going to be significantly larger. So, the round off error in the solution depends only on the round off error in my last iteration, since it means that the round off errors in the previous iterations are self correcting that is they cancel each other out.

It also means that it is not necessary to compute with full accuracy in the first this is a very, very important result, because a in lots and lots of places it is used out all in multi dimensions this has got very important implications. So, it is not necessary to compute with full accuracy in the first few iterations, so we will see I mean if I talked about this here that if I am going to talk about it later on it has got very important implications.

(Refer Slide Time: 40:45)

**Effect of round off on convergence**

- For sufficiently large number of iterations,  $n$ , the round off error is the dominant contribution to  $|\bar{x}_{n+1} - \alpha|$
- Increase in the number of iterations then do not lead to any significant change in the truncation error and error remains at a constant magnitude of  $\frac{\delta}{(1-m)}$
- Next, let us recall that the convergence estimates we got for the Newton Raphson and Secant methods hold true only for simple roots. For multiple roots, the Newton Raphson method for example, is only linearly convergent.

 NPTEL

For sufficiently large number of iterations  $n$  the round off error is the dominant contribution to  $\bar{x}_{n+1} - \alpha$ , you can see that, because as the number of iterations goes up the truncation error is going to, become smaller and smaller.

(Refer Slide Time: 40:57)

**Effect of round off on convergence**

Let us denote by  $\bar{x}_1, \bar{x}_2, \dots, \bar{x}_n$  the sequence of approximations and let the error at each stage due to roundoff be denoted by  $\delta_i$ . Then  $\bar{x}_{n+1} = \phi(\bar{x}_n) + \delta_n, n = 0, 1, \dots$ . Subtracting the converged sequence  $\alpha = \phi(\alpha)$  from both sides, we get:

$$\bar{x}_{n+1} - \alpha = \phi(\bar{x}_n) - \alpha + \delta_n = \phi'(\xi_n)(\bar{x}_n - \alpha) + \delta_n, \xi_n \in [\bar{x}_n, \alpha]$$

Subtracting  $\phi'(\xi_n)\bar{x}_{n+1}$  from both sides and rearranging terms, we get:  $[1 - \phi'(\xi_n)](\bar{x}_{n+1} - \alpha) = \phi'(\xi_n)(\bar{x}_n - \bar{x}_{n+1}) + \delta_n$

Assuming bounds on both derivative and error i.e.  $|\phi'(\xi_n)| \leq m < 1$  and  $|\delta_n| < \delta$ , we get:  $|\bar{x}_{n+1} - \alpha| < \frac{m|\bar{x}_n - \bar{x}_{n+1}|}{(1-m)} + \frac{\delta}{(1-m)}$

Because, my solution my n plus 1 has an n increases my x bar n plus 1 becomes a better and better approximation to my root alpha. So, as I increase the number of iterations the truncation error is going to become smaller and smaller, it is actually as I go to alpha the truncation error is going to go to 0. But, my round off error is not going to go to 0, my round off error is also always going to be there.

(Refer Slide Time: 41:37)

**Effect of round off on convergence**

- For sufficiently large number of iterations, n, the round off error is the dominant contribution to  $|\bar{x}_{n+1} - \alpha|$
- Increase in the number of iterations then do not lead to any significant change in the truncation error and error remains at a constant magnitude of  $\frac{\delta}{(1-m)}$
- Next, let us recall that the convergence estimates we got for the Newton Raphson and Secant methods hold true only for simple roots. For multiple roots, the Newton Raphson method for example, is only linearly convergent.

So, increase in the number of round off error is the dominant contribution to x bar n plus 1 minus alpha, so increase in the number of iterations, then do not lead to any significant

change in the truncation error, because as I am reaching the limit of the sequence the contribution of the truncation error is becoming negligibly small. But, my round off error remains at a constant magnitude of  $\delta(1 - m)$ , where  $\delta$  is a bound on the round off error in the last iteration.

Next, let us recall that the convergence estimates we got for the Newton Raphson and Secant method hold true only for simple roots, for multiple roots the Newton Raphson method for example, is only linearly convergent. So, let us talk about improving the convergence of Newton Raphson for multiple roots, but at this point I want to talk a little bit about this error bound a little bit more.

So, basically we saw that because this error bound depends only on the error in the last and the round off error in the last iteration, so it is not important for the first beginning iterations to be calculated with great accuracy, because their accuracy is not going to determine the round off error. A round off error is going to be, so this has lots of implications because for instance, when you have multiple, when we are solving a non-linear problem in multiple dimensions and we want to use a Newton Raphson update formula.

Newton Raphson update formula as you can see in the we will see that in more detail later, but that means the cost of the update is the cost of calculating the derivatives. So, if we have a multi dimensional function the derivative the Jacobian is no longer going to be a simple a single term it is going to be a  $n$  by  $n$  term, so the Jacobian forming that Jacobian and if necessary inverting it, so those are extremely, extremely expensive operations.

So, what does that mean; so the accuracy is not that important in the first iterations, first few iterations accuracy only becomes important towards the end; that means, that towards the beginning it is also not necessary for me to calculate all those derivatives to a great deal of accuracy. And because of that there are things like modified Newton quasi Newton and things like that we try to approximate those derivatives, so that they are easier cheaper to calculate, to reduce the cost.

Because, we know that what we do in the beginning of that beginning of an iteration it is not going to be that crucial, unless I do something absolutely weird that is not going to be which makes my solution diverge and that is not going to be that crucial, so that is

why this is very important. Now, let us let us look at multiple roots, we recall that the convergence estimates we got for the Newton Raphson and secant methods hold true only for simple roots, for multiple roots the Newton Raphson method for example, is only linearly convergent.

(Refer Slide Time: 45:23)

### Improving convergence for multiple roots

Recall that a root  $\alpha$  of  $f(x) = 0$  is said to have a multiplicity  $q$  if  $0 \neq |g(\alpha)| < \infty$  where  $g(x) = (x - \alpha)^{-q} f(x)$

- However by a slight modification of the iteration algorithm, it is possible to recover quadratic convergence
- Quadratic convergence is recovered with the update formula:
 
$$x_{n+1} = x_n + q h_n, h_n = -\frac{f(x_n)}{f'(x_n)}$$

 However this assumes that the number of roots  $q$  is known a priori – which is not usually the case

So, is it possible to improve the convergence properties at multiple roots well let us take a look at that, so we call that a root alpha of f of x is equal to 0 is said to have a multiplicity q, if we can write there exists a function g of x, which is equal to x minus alpha to the power minus q times f of x. Where, q is the multiplicity of the root alpha and g of alpha is bounded, that is mod of g of alpha is less than infinity is greater than 0.

So, what this basically means that there exists a function g of x which can be written as if I take out the q roots of alpha, if I take my original function of f of x I divided by it x minus alpha to the power q, I take out the q roots of f of x. The function what is means let me call that g of x and that function g of x exists, what does it mean exists; that means, that g of alpha is not zero and is not infinity it is bounded right and it is not zero so; that means, there exists a function g of x, which I can write like that.

In case f of x has root of multiplicity q; however, so we saw that for the Newton Raphson method if it has multiple roots if it has two roots for instance, then we are going to get linear convergence. However, by slight modification of the iteration algorithm it is possible to recover quadratic convergence, what is that slight modification well

originally we had  $x^{n+1}$  is equal to  $x^n$  for the Newton Raphson method, where  $x^{n+1}$  is equal to  $x^n - f(x)/f'(x)$ .

So, now, I am saying that instead of having  $x^{n+1}$  equal to  $x^n - f(x)/f'(x)$  I am going to have  $x^{n+1}$  is equal to  $x^n + q \cdot f(x)/f'(x)$ , where  $q$  is the number of is the multiplicity of the root  $\alpha$ . So, that is well fine and good that, but assume is that I knew a priori beforehand, how many roots there are right it assumes that I know beforehand what is the value of  $q$ , , but suppose we do not know that then what can we do.

### Improving convergence for multiple roots

- Alternatively, convergence can be improved by adopting the following algorithm, which supposes  $f(x)$  is  $q$  times differentiable in a nbd. of root  $\alpha$  of multiplicity  $q$

Since  $f(x) = g(x)(x-\alpha)^q$ ,  $f'(x) = g'(x)(x-\alpha)^q + g(x)q(x-\alpha)^{q-1}$   
Hence,  $f'(\alpha) = 0$ . Similarly  $f^{(j)}(\alpha) = 0 \forall j < q$ .  
Thus we can write :

$$f(x) = \frac{(x-\alpha)^q f^{(q)}(\xi)}{q!} \text{ and } f'(x) = \frac{(x-\alpha)^{q-1} f^{(q)}(\xi)}{(q-1)!} \text{ where } \xi \in [x, \alpha]$$

Alternatively, convergence can be improved by adopting the following algorithm, which supposes that  $f$  of  $x$  is  $q$  times differentiable in a neighborhood of root  $\alpha$  of multiplicity  $q$ . Set let us suppose that the function is differentiable at least  $q$  times,  $q$  being the multiplicity, it assumes that  $q$  is  $f$  is differentiable. In that case since  $f$  of  $x$  is equal to  $g$  of  $x$   $x$  minus  $\alpha$  to the power  $q$ , since  $\alpha$  is a root of a multiplicity  $q$ .

So, I can write  $f$  prime of  $x$  is equal to  $g$  prime of  $x$   $x$  minus  $\alpha$  to the power  $q$  plus  $g$  of  $x$  times  $q$  times  $x$  minus  $\alpha$   $q$  minus  $1$  just taking the derivative, so  $f$  prime of  $\alpha$  is equal to  $0$ . Why? Substitute  $\alpha$  here both sides these two terms go to  $0$ , so  $f$  prime of  $\alpha$  is equal to  $0$ . Similarly,  $f$  to the power  $j$   $\alpha$  is going to be equal to  $0$ , for any  $j$  less than  $q$  you can see that, because if you take derivatives up to less than  $q$ , there is

always going to be a term  $x$  minus  $\alpha$ , in the right hand side and when  $x$  becomes equal to  $\alpha$  that term is going to go to 0.

So,  $f^{(j)}(\alpha)$  is going to be 0, for all  $j$  less than  $q$  then we can write  $f$  of  $x$  again doing a Taylor series expansion of  $f$  of  $x$  about  $\alpha$ . Then  $f$  of  $x$  can be written like this, because again  $f$  of  $\alpha$  is going to be 0,  $f'$  of  $\alpha$  is the second term in the Taylor series  $f''$  of  $\alpha$  is going to be 0,  $f'''$  of  $\alpha$  is going to be 0, up to order  $j$  where  $j$  is less than  $q$ .

So, all those terms in the Taylor series are going to go to 0 and the only term and the term which is going, which is the first term which is not going to go to 0, must have derivative of order  $q$ , because for all  $j$  less than  $q$   $f^{(j)}$  of  $\alpha$  is equal to 0. So, in the Taylor series we are going to evaluate this derivative at  $\alpha$  that is why expanding this Taylor series about  $\alpha$ . So, all those  $j$  terms  $j$  less than  $q$  are going to go to 0, so the first term that is going to survive is going to be this term.

And if you evaluate repeat this term as the remainder term, we can write it as  $x$  minus  $\alpha$  to the power  $q$  times of  $f^{(q)}$  derivative of  $f$  evaluated at  $\xi$  where  $\xi$  belongs to the interval  $x$  alpha divided by factorial of  $q$ . So, that becomes my  $f$  of  $x$ , and what is my  $f'$  of  $x$   $f''$  of  $x$  I just take the derivative of both sides  $x$  minus  $\alpha$   $q$  minus 1  $f^{(q)}$  of  $\xi$   $q$  minus 1 factorial where  $\xi$  belongs to  $\alpha$ , so now, what do we have?

### Improving convergence for multiple roots

Let us substitute  $u(x) = \frac{f(x)}{f'_q(x)}$ . Then we have:

$$\lim_{x \rightarrow \alpha} \frac{u(x)}{(x-\alpha)} = \frac{\frac{1}{q!} (x-\alpha)^q f^{(q)}(\xi)}{\frac{1}{(q-1)!} (x-\alpha)^{q-1} f^{(q)}(\xi)} \times \frac{1}{(x-\alpha)} = \frac{1}{q}$$

- Thus the equation  $u(x) = 0$  has a simple root at  $x = \alpha$  and this allows previously discussed iterative methods such as the Newton Raphson and Secant algorithms to be applied to this equation

Let us write  $u$  of  $x$  is equal to  $f$  of  $x$  by  $f$  prime of  $x$ , then if we write  $u$  of  $x$  by divided by  $x$  minus  $\alpha$ , and then if I take the limit as  $x$  goes to  $\alpha$  what is  $u$  of  $x$   $u$  of  $x$  is  $f$  of  $x$  by  $f$  prime of  $x$ .

(Refer Slide Time: 51:36)

### Improving convergence for multiple roots

- Alternatively, convergence can be improved by adopting the following algorithm, which supposes  $f(x)$  is  $q$  times differentiable in a nbd. of root  $\alpha$  of multiplicity  $q$

Since  $f(x) = g(x)(x-\alpha)^q$ ,  $f'(x) = g'(x)(x-\alpha)^q + g(x)q(x-\alpha)^{q-1}$   
Hence,  $f'(\alpha) = 0$ . Similarly  $f^{(j)}(\alpha) = 0 \forall j < q$ .

Thus we can write :

$$f(x) = \frac{(x-\alpha)^q f^{(q)}(\xi)}{q!} \text{ and } f'(x) = \frac{(x-\alpha)^{q-1} f^{(q)}(\xi)}{(q-1)!} \text{ where } \xi \in [x, \alpha]$$

So,  $f$  of  $x$  is this  $f$  prime of  $x$  is this, so if I divide this by this.

(Refer Slide Time: 51:42)

### Improving convergence for multiple roots

Let us substitute  $u(x) = \frac{f(x)}{f'_q(x)}$ . Then we have :

$$\lim_{x \rightarrow \alpha} \frac{u(x)}{(x-\alpha)} = \frac{\frac{1}{q!} (x-\alpha)^q f^{(q)}(\xi)}{\frac{1}{(q-1)!} (x-\alpha)^{q-1} f^{(q)}(\xi)} \times \frac{1}{(x-\alpha)} = \frac{1}{q}$$

- Thus the equation  $u(x) = 0$  has a simple root at  $x = \alpha$  and this allows previously discussed iterative methods such as the Newton Raphson and Secant algorithms to be applied to this equation

And I divide that by  $x$  minus  $\alpha$  I am going to get one by  $q$  I am going to get one by  $q$ , so what does that mean? That means, that the equation  $u$  of  $x$  has a simple root at  $x$  is equal to  $\alpha$ . Why? Because, if I take  $u$  of  $x$  and divide it by  $x$  minus  $\alpha$  then in the

limit as  $x$  goes to  $\alpha$ , I am getting a constant. If this was not a simple root, then there would have been terms like,  $x$  to the power minus  $\alpha$  on this side, I have to get  $u$  of  $x$  I am dividing it by  $x$  minus  $\alpha$ .

If  $u$  of  $x$  had more than one root at  $\alpha$ , then I would have had  $x$  minus  $\alpha$  on the I would have had some  $x$  minus  $\alpha$  surviving, this quotient would have had  $x$  minus  $\alpha$ . And then when  $x$  went to  $\alpha$  that would have gone to 0, but we are saying that that is not going to 0, that is actually going to 1 by  $q$ ; that means, a  $u$  of  $x$  must have only 1 root at  $\alpha$ , because after I divided by  $x$  minus  $\alpha$  and I take the limit  $x$  goes to  $\alpha$  it goes to a constant.

It does not go to 0; that means,  $u$  of  $x$  has a simple root at  $x$  is equal to  $\alpha$  and this allows since it has a simple root; that means, I can use my Newton Raphson, Secant algorithms, and this equation and recover my original order of convergence, which is for the Newton Raphson I am going to get quadratic convergence. So, if we define a new function,  $u$  of  $x$  which is  $f$  of  $x$  by  $f$  prime of  $x$ , this was my original function and then if an  $u$  of  $x$  I do my new Newton iteration, if I do my newton iteration in  $u$  of  $x$  I am going to get quadratic convergence. Like for  $f$  of  $x$  I did not have quadratic convergence, so that that is a very easy way of converting,  $u$  of  $f$  of  $x$  to a function, such that I have quadratic convergence.

(Refer Slide Time: 53:57)

### Improving convergence for multiple roots

Supposing Newton Raphson is being used, then we can use the usual Newton Raphson iterative scheme to find the root of  $u(x) = 0$ :

$$x_{n+1} = x_n - \frac{u(x_n)}{u'(x_n)}$$

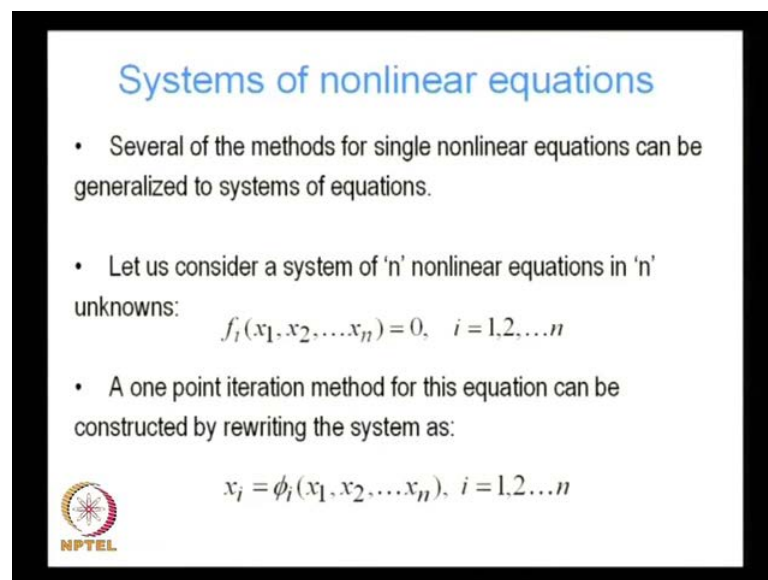

Thus instead of finding the root of  $f(x) = 0$  using Newton Raphson we find roots of  $u(x) = 0$ .

Now we are assured of quadratic convergence. In addition, we are assured that the root of  $u(x) = 0$  is also the root of  $f(x) = 0$  by construction.

Suppose, Newton Raphson is being used, then we can use the usual Newton Raphson scheme to find the root of  $u$  of  $x$  is equal to 0, so this is my usual Newton Raphson scheme, but now I am using a term  $u$ . Then instead of finding the root of  $f$  of  $x$  is equal to 0, by using Newton Raphson to find the roots of  $u$  of  $x$  is equal to 0. So, now, we are assured of quadratic convergence in addition, we are assured that the root of  $u$  of  $x$  is also root of  $f$  of  $x$ , because that we saw by construction. So, even though we have multiple roots, we have a easy way of converting it into improving the order of convergence by writing an another function, which is just a the original function divided by it is derivative.

**Systems of nonlinear equations**

- Several of the methods for single nonlinear equations can be generalized to systems of equations.
- Let us consider a system of 'n' nonlinear equations in 'n' unknowns:  
$$f_i(x_1, x_2, \dots, x_n) = 0, \quad i = 1, 2, \dots, n$$
- A one point iteration method for this equation can be constructed by rewriting the system as:  
$$x_i = \phi_i(x_1, x_2, \dots, x_n), \quad i = 1, 2, \dots, n$$

 NPTEL

So, I thought we will go we will have a system of that will continue with that in the next class, where we are going to talk about systems of non-linear equations.

Thank you.
