**Module – 6.2**  
**Lecture - 06**  
**Linear Algebra - Basic Definitions**

Now, from here on we will go on to something even more basic. We will start defining some basic definitions from linear algebra and these are again important for something that I need in the next lecture. So, let us start with this.

(Refer Slide Time: 00:27)

• We will see some more examples where eigenvectors are important, but before that let's revisit some basic definitions from linear algebra.

I mean, in the process we all just see, why the eigenvectors are important for us in this course? Ok.

(Refer Slide Time: 00:33)

**Basis**  
A set of vectors  $\in \mathbb{R}^n$  is called a basis, if they are linearly independent and every vector  $\in \mathbb{R}^n$  can be expressed as a linear combination of these vectors.

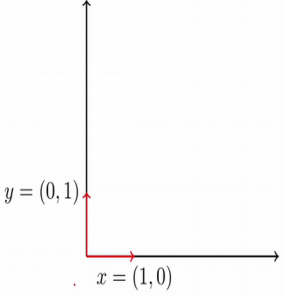

**Linearly independent vectors**  
A set of  $n$  vectors  $v_1, v_2, \dots, v_n$  is linearly independent if no vector in the set can be expressed as a linear combination of the remaining  $n - 1$  vectors.  
In other words, the only solution to  $c_1 v_1 + c_2 v_2 + \dots + c_n v_n = 0$  is  $c_1 = c_2 = \dots = c_n = 0$  ( $c_i$ 's are scalars)

Prof. Mitesh M. Khapra CS7015 (Deep Learning) : Lecture 6

So, how many of you know what a basis is. So, a set of vectors belonging to  $\mathbb{R}^n$  is called a basis. If they are linearly independent right, and every vector in  $\mathbb{R}^n$  can be expressed as a linear combination of these vectors. So, a set of  $n$  vectors  $v_1$  to  $v_n$  is linearly independent. If no vector in the set can be expressed as a linear combination of the remaining  $n$  minus 1 vectors ok. So, a more weird we are stating it that. So, that everyone get confuse is that if you take this linear combination ok.

The only solution to this is all the  $c_i$ 's is equal to 0 and that make perfect sense right, that is that same as that linear combination, linear independence and all that thus, is make sense to everyone ok. So, what does linear independence mean that any vector from this set cannot be expressed as the linear combination of the other set; other vectors in the set and a more formal way of saying that is this ok. Everyone gets this what is linear independence.

(Refer Slide Time: 01:35)

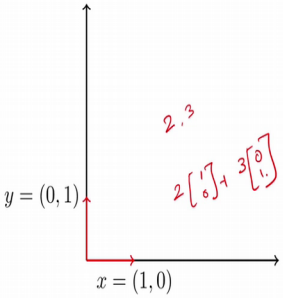

- For example consider the space  $\mathbb{R}^2$
- Now consider the vectors
$$x = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \text{ and } y = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$
- Any vector  $\begin{bmatrix} a \\ b \end{bmatrix} \in \mathbb{R}^2$ , can be expressed as a linear combination of these two vectors i.e
$$\begin{bmatrix} a \\ b \end{bmatrix} = a \begin{bmatrix} 1 \\ 0 \end{bmatrix} + b \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$
- Further,  $x$  and  $y$  are linearly independent.  
(the only solution to  $c_1x + c_2y = 0$  is  $c_1 = c_2 = 0$ )

14/71

Prof. Mitesh M. Khapra CS7015 (Deep Learning) : Lecture 6

Now, let us consider some very stupid examples, again the space  $\mathbb{R}^2$  and we consider these 2 vectors  $\begin{bmatrix} 1 \\ 0 \end{bmatrix}$  and  $\begin{bmatrix} 0 \\ 1 \end{bmatrix}$ . Are they linearly independent? Yes, they cannot be expressed as a multiple of each other right. Now, any vector  $\begin{bmatrix} a \\ b \end{bmatrix}$  belonging to  $\mathbb{R}^2$  can be expressed as a linear combination of these 2 vectors ok. And  $x$  and  $y$  are linearly independent the only solution is  $c_1x + c_2y = 0$  is  $c_1 = c_2 = 0$ ; What about if I move to  $\mathbb{R}^3$   $\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$   $\begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}$  and  $\begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$ . So,  $x$ ,  $y$  and  $z$  axis right are the unit vector.

(Refer Slide Time: 02:12)

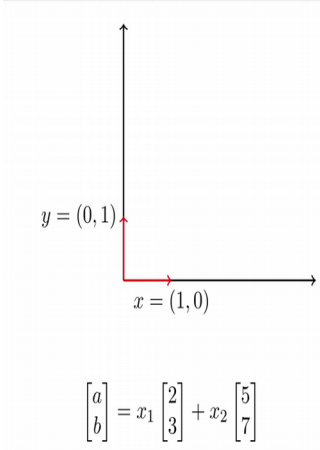

- In fact, turns out that  $x$  and  $y$  are unit vectors in the direction of the co-ordinate axes.
- And indeed we are used to representing all vectors in  $\mathbb{R}^2$  as a linear combination of these two vectors.

14/71

Prof. Mitesh M. Khapra CS7015 (Deep Learning) : Lecture 6

So, in that  $x$  and  $y$  turns to be unit vectors in the direction of the coordinate axis. And we are used to representing every point in  $\mathbb{R}^2$  as a linear combination of these 2 vector is that exactly what I what we do. So, when we say that I have a point 2 coma 3, I am actually telling you that the point is 2 1 0 plus 3 0 1 right. I am expressing at are the linear combination of the coordinate axis.

(Refer Slide Time: 02:38)

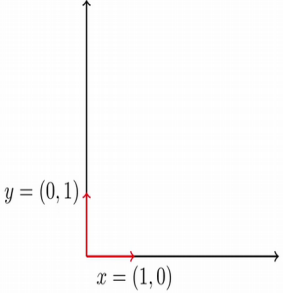

- In fact, turns out that  $x$  and  $y$  are unit vectors in the direction of the co-ordinate axes.
- And indeed we are used to representing all vectors in  $\mathbb{R}^2$  as a linear combination of these two vectors.
- But there is nothing sacrosanct about the particular choice of  $x$  and  $y$ .
- We could have chosen any 2 linearly independent vectors in  $\mathbb{R}^2$  as the basis vectors.
- For example, consider the linearly independent vectors,  $[2, 3]^T$  and  $[5, 7]^T$ . See how any vector  $[a, b]^T \in \mathbb{R}^2$  can be expressed as a linear combination of these two vectors.
- We can find  $x_1$  and  $x_2$  by solving a system of linear equations.

15/71

But now this nothing sacrosanct about  $x$  and  $y$  right; I could have chosen just about any other axis ok. So, in particular we could have chosen this as our basis are these 2 vectors linearly independent can any vector and  $\mathbb{R}^2$  be expressed as a linear combination of these 2 vectors sure. So, I give you a vector  $a$   $b$ , how do you going to express it as a linear combination of these 2 vectors? So, you will do it this way right. How will you find that values are the  $x_1$  and  $x_2$ ; so, other linear system of linear equations right.

(Refer Slide Time: 03:09)

$y = (0, 1)$   
 $x = (1, 0)$

$a = 2x_1 + 5x_2$   
 $b = 3x_1 + 7x_2$

- In fact, turns out that  $x$  and  $y$  are unit vectors in the direction of the co-ordinate axes.
- And indeed we are used to representing all vectors in  $\mathbb{R}^2$  as a linear combination of these two vectors.
- But there is nothing sacrosanct about the particular choice of  $x$  and  $y$ .
- We could have chosen any 2 linearly independent vectors in  $\mathbb{R}^2$  as the basis vectors.
- For example, consider the linearly independent vectors,  $[2, 3]^T$  and  $[5, 7]^T$ . See how any vector  $[a, b]^T \in \mathbb{R}^2$  can be expressed as a linear combination of these two vectors.
- We can find  $x_1$  and  $x_2$  by solving a system of linear equations.

15/71

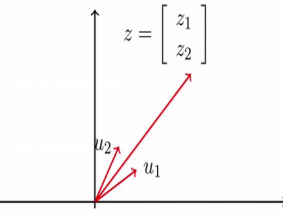

Prof. Mitesh M. Khapra CS7015 (Deep Learning) : Lecture 6

So, this is what you will do. I know all are good in doing this and what do we actually do when we do this? What is the algorithm that we use? How do we solve this? What is the algorithm that you use solving this?

Student: Gaussian elimination

Gaussian elimination right, in 2 variables of course we do not call it an algorithm. That is what we did in 8 standard or something, but when we come to engineering we call it Gaussian elimination right; So, the same algorithm ok.

(Refer Slide Time: 03:29)

$z = \begin{bmatrix} z_1 \\ z_2 \end{bmatrix}$

- In general, given a set of linearly independent vectors  $u_1, u_2, \dots, u_n \in \mathbb{R}^n$ , we can express any vector  $z \in \mathbb{R}^n$  as a linear combination of these vectors.

$$z = \alpha_1 u_1 + \alpha_2 u_2 + \dots + \alpha_n u_n$$

$$\begin{bmatrix} z_1 \\ z_2 \\ \vdots \\ z_n \end{bmatrix} = \alpha_1 \begin{bmatrix} u_{11} \\ u_{12} \\ \vdots \\ u_{1n} \end{bmatrix} + \alpha_2 \begin{bmatrix} u_{21} \\ u_{22} \\ \vdots \\ u_{2n} \end{bmatrix} + \dots + \alpha_n \begin{bmatrix} u_{n1} \\ u_{n2} \\ \vdots \\ u_{nn} \end{bmatrix}$$

$$\begin{bmatrix} z_1 \\ z_2 \\ \vdots \\ z_n \end{bmatrix} = \begin{bmatrix} u_{11} & u_{21} & \dots & u_{n1} \\ u_{12} & u_{22} & \dots & u_{n2} \\ \vdots & \vdots & \ddots & \vdots \\ u_{1n} & u_{2n} & \dots & u_{nn} \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \vdots \\ \alpha_n \end{bmatrix}$$

- We can now find the  $\alpha_i$ s using Gaussian Elimination (Time Complexity:  $O(n^3)$ )

16/71

Prof. Mitesh M. Khapra CS7015 (Deep Learning) : Lecture 6

So, in general given a set of linearly independent vectors, we can express any vector that belonging to  $\mathbb{R}^n$  as a linear combination of these vectors right. I can say  $z$  is equal to  $\alpha_1 u_1 + \alpha_2 u_2$  and so on given  $\alpha_1$  to  $\alpha_n$  are linearly independent ok. So; that means, any vector in  $\mathbb{R}^n$  can be expressed using these vectors which form the basis of  $\mathbb{R}^n$  does that make sense ok. That is why call the basis vector because, anything else these are the fundamental vectors using these anything else can be expressed in that space it is that clear ok.

So, this is how it will be. How do I write this in matrix notation  $A$ ? There are lot of these and these thing I do not really understand what you mean by that ok, yeah good. So, this is what you mean. So, that we writing same in matrix notation and now this is again a dash a system of linear equation there was a lot of space to fill and one dash good. So, system of linear equation and again you can solve them using.

Student: Gaussian elimination

Gaussian elimination, what is the complexity of Gaussian elimination. Let us see options right  $n \times n$  square  $n^3$  [FL],  $n^3$  right the Gaussian elimination the complexity is  $O(N^3)$  right. And I am not doing all this just to the sake of time pass I have a point of make which I will make on the next class right. So now, this was for any basis; that means, if you have any  $n$  linear independent vectors.

Now, I will consider a special basis where instead of  $n$  linearly independent vectors. In addition, these vectors are also orthogonal ok. Orthogonal vectors are linearly independent ok. So, a set of orthogonal vectors are linearly independent, but the converse is not all this right ok.

(Refer Slide Time: 05:12)

$z = \begin{bmatrix} a \\ b \end{bmatrix}$

$\alpha_1 = |z| \cos \theta = |z| \frac{z^T u_1}{|z| |u_1|} = z^T u_1$

Similarly,  $\alpha_2 = z^T u_2$ .  
 When  $u_1$  and  $u_2$  are unit vectors along the co-ordinate axes

$z = \begin{bmatrix} a \\ b \end{bmatrix} = a \begin{bmatrix} 1 \\ 0 \end{bmatrix} + b \begin{bmatrix} 0 \\ 1 \end{bmatrix}$

- Now let us see if we have orthonormal basis.
- $u_i^T u_j = 0 \forall i \neq j$  and  $u_i^T u_i = \|u_i\|^2 = 1$
- Again we have:
 
$$z = \alpha_1 u_1 + \alpha_2 u_2 + \dots + \alpha_n u_n$$

$$u_1^T z = \alpha_1 u_1^T u_1 + \dots + \alpha_n u_1^T u_n$$

$$= \alpha_1$$
- We can directly find each  $\alpha_i$  using a dot product between  $z$  and  $u_i$  (time complexity  $O(N)$ )
- The total complexity will be  $O(N^2)$

Prof. Mitesh M. Khapra CS7015 (Deep Learning) : Lecture 6

So now, let us see what if we have an orthonormal basis; that means, a basis consisting of orthonormal vectors. So, orthonormal is combination of 2 words ortho means, the 2 vectors are orthogonal and normal means all the vectors are unit vectors; that means, I am normalized them by their magnitude fine.

So, what is the condition that holds  $u_i^T u_j$  is equal to 0? If  $i$  is not equal to  $j$  and  $u_i^T u_i$  is equal to 1. Ok now, what happens in this special case, so we have this again we can express any vectors that as a linear combination of these. Ok now, let me try to do this I am just pre multiplying this equation by  $u_1^T$ . What happens on the right hand side everything disappears all of the this terms will disappear because, they are of the form  $u_i^T u_j$  where  $i$  is not equal to  $j$  and the first term is.

Student: One.

One, so what remains  $\alpha_1$ . So, you can directly find  $\alpha_1$  using a dot product of 2 vectors. What is the complexity of this operation  $n$  the is just  $n$  products ok? Now how many such alphas do we need to find.

Student: (Refer Time: 6:09).

$n$  of those. So, what is the complexity of  $d \times n$  square. So, that is now you see why an orthonormal basis is a very convenient basis, you can get all these coefficients just by doing a dot product between 2 vectors and later on I will show you that you might not

need all of these. You might just need some subset  $k$  of these right so; that means, you just do  $k$  of these dot products and get these values. So, do you now understand the meaning of what is why, why do I say it is orthonormal basis is the most convenient basis that you can hope for right ok.

So, the another way of looking it right at it is again just to make few more comfortable with vectors and projections and so on right. So, this was your original point  $z$   $z$  which is a comma  $b$  right. And how do you actually draw that vector that, this is  $a$  and this is  $b$  ok. So, how do you find the coordinates actually you projects on to your basis vectors which were these  $x$  and  $y$  vectors. That is how you found the components along those the coefficient along those.

Now, instead of this  $x$  and  $y$ , I have any other set of vectors which is  $u_1$  and  $u_2$  and I will do the same thing I will project this on to  $u_1$  ok. I will project this on to  $u_2$  and that projection will give me  $\alpha_1$  and  $\alpha_2$  right. So now, what is  $\alpha_1$  and that sense this is  $z$ , this is  $\alpha_1$  and this is  $\theta$  right. So,  $\alpha_1$  is equal to  $z$  into  $\cos \theta$  ok. And what this  $\cos \theta$ ? Ok. So, again you arrive at the same thing fine.

So, essentially taking a projection of a vector on to your basis is that. Fine to everyone, there is just to difference arriving at the same formula ok. That  $\alpha$  is are given by a dot product between the basis vector and your original vector fine.

(Refer Slide Time: 08:08)

---

**Remember**  
An orthogonal basis is the most convenient basis that one can hope for.

< > < > < > < > < > < >

Prof. MITESH M. KHAPRA CS7015 (Deep Learning) : Lecture 6

So, an orthogonal basis is the more convenient basis that you can hope for. That is the point, which I wanted to have you are convinced about that ok.

(Refer Slide Time: 08:16)

**Theorem 1**  
The eigenvectors of a matrix  $A \in \mathbb{R}^{n \times n}$  having distinct eigenvalues are linearly independent.  
**Proof:** [See here](#)

**Theorem 2**  
The eigenvectors of a square symmetric matrix are orthogonal.  
**Proof:** [See here](#)

- But what does any of this have to do with eigenvectors?
- Turns out that the eigenvectors can form a basis.
- In fact, the eigenvectors of a square symmetric matrix are even more special.

$\frac{u_1}{\|u_1\|} \quad u_2 \quad u_3$

NPTEL Prof. Mitesh M. Khapra CS7015 (Deep Learning) : Lecture 6

Now, but what does any of this have to do with eigenvectors. I started off with eigenvectors, I proved one property there and then I came to this linear algebra basic definitions and what a basis is set of linear independent vectors. And I eventually showed you that, an orthonormal basis is the most convenient basis that you can hope. So, what does any of this have to do with eigenvector.

Student: (Refer Time: 8:50).

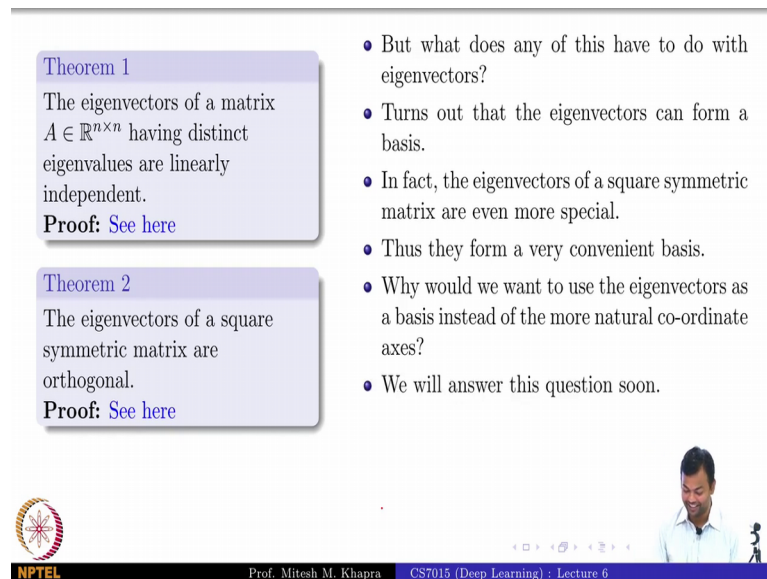

Always for us, square symmetric matrix right, why do you care about square symmetric matrix? Not sure yet. So, we get to that ok. So first of all, it turns out the eigenvectors can form a basis and this is for any matrix. So, the eigenvectors of a matrix having distinct eigenvalues are linearly independent ok.

So, does every matrix, if I have an  $n \times n$  matrix will it have  $n$  eigenvectors? No, it can have less than or equal to eigenvector depending on the (Refer Time: 9:15). So, what is this saying is that if these eigenvectors are having distinct eigenvalues ok. Then these eigenvectors would be linearly independent, fine and turns out that for a square symmetric matrix that is the even more special, the eigenvector of a square symmetric matrix are.

Student: Orthogonal.

Orthogonal right and we already know that orthogonal is good right. So, remember, when we have orthogonal we do not really care about orthogonal. Because, that is it is a simple operation, if you have a set of vectors  $u_1, u_2, u_3$  which are orthogonal, you can just divide them by the magnitudes and just get a set of orthonormal vectors right. So, orthogonal and orthonormal, I will use it interchangeably ok. And, whatever I done thus they form a very convenient basis. So, the eigenvectors of a square symmetric matrix form a very convenient basis.

(Refer Slide Time: 09:51)

The slide content is as follows:

**Theorem 1**  
The eigenvectors of a matrix  $A \in \mathbb{R}^{n \times n}$  having distinct eigenvalues are linearly independent.  
**Proof:** [See here](#)

**Theorem 2**  
The eigenvectors of a square symmetric matrix are orthogonal.  
**Proof:** [See here](#)

- But what does any of this have to do with eigenvectors?
- Turns out that the eigenvectors can form a basis.
- In fact, the eigenvectors of a square symmetric matrix are even more special.
- Thus they form a very convenient basis.
- Why would we want to use the eigenvectors as a basis instead of the more natural co-ordinate axes?
- We will answer this question soon.

The slide also features the NPTEL logo, a small image of a man, and navigation icons. The footer contains the text: Prof. Mitesh M. Khapra CS7015 (Deep Learning) : Lecture 6

So, that is how I connect the parts which was about the eigenvectors to the second part, which was about basis. And why would we want to do this and we already we had a coordinate axis that is the very good basis  $1 \ 0 \ 0 \ 0 \ 0 \ 1 \ 0 \ 0 \ 1$  and  $n$  dimension similarly.

So, why should I want to use the different basis? I have said that eigenvectors is a very convenient basis, but why do I care about it. I already have a very, very convenient basis which is just these 1 or 2 vectors are along these directions right. So, why do I care about a different basis? Ok, I understand that I that is there somewhere, but something more than that that is one advantage which I will talk about. What else more interesting? Ok, in what sense I love the power which comes with my job right. That you give a right answer and still I can embarrass you know. So, that is correct actually.
