Lecture – 11
Solvability of a Linear System, Linear Span, Basis II

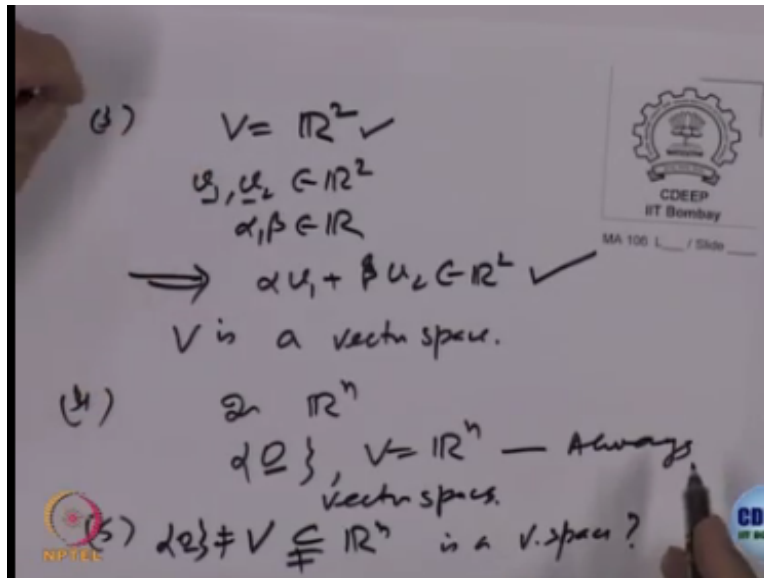

Can you think of some other subspace in \mathbb{R}^2 , only every line through the origin is the subspace, this was one of them, I fix X_0 , X_0 could be anything, right, so there is another possibility that means \mathbb{R} lines passing through the origin in \mathbb{R}^2 are vector spaces in \mathbb{R}^2 , right, some other example; so I am just looking at \mathbb{R}^2 , simple one, you can visualise.

(Refer Slide Time: 01:02)

So, let us look at another example, let us look at the zero vector alone, so that is V , is that a vector space? Only one element is there, what all you multiply, it will always be 0 and it will be staying inside, so is a subspace, so oh sorry is a vector space.

(Refer Slide Time: 01:37)

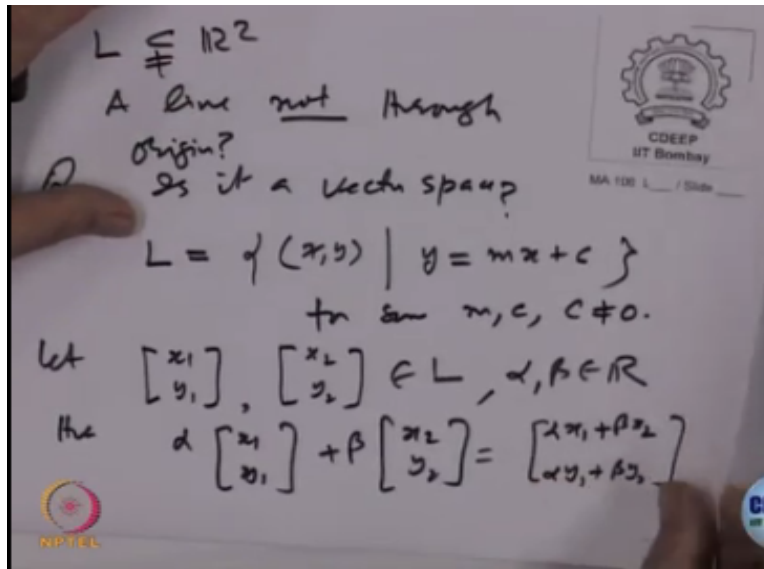

Let us look at the whole space plane or so let us look at third example, $V = \mathbb{R}^2$, V is the substrate of \mathbb{R}^2 , right, V is the substrate of \mathbb{R}^n , so I am looking at specialising $n = 2$, what about $V = \mathbb{R}^2$, is that a vector space, yes it is because if we take any 2 vectors, right, multiply alpha, so right, if V_1, V_2 belong to \mathbb{R}^2 and alpha, beta belong to \mathbb{R} , does this imply that $\alpha V_1 + \beta V_2$, is again in \mathbb{R}^2 ; yes, it is the vector again, right.

So V is; $V = \mathbb{R}^2$ is a vector space, so in \mathbb{R}^2 or in \mathbb{R}^n , so you can write generally in \mathbb{R}^n , look at the zero vector and look at $V = \mathbb{R}^n$, these are always vector spaces, right, so these are called trivial vector spaces, you do not have to verify anything they are obviously given right, there obvious examples of vector spaces, interesting thing; it becomes when you want a proper subset of \mathbb{R}^n and you want say it is a vector space.

So, interesting thing is V proper in \mathbb{R}^n and it should not be equal to 0 because 0 is always; right, right, A is a vector space, when is it a vector space? So, the examples I have been trying to give you are in \mathbb{R}^2 , every line passing through origin is a vector space, zero; origin itself is a vector space; zero vector, whole plane is a vector space, you ask a question is there any other subspace, is there any other vector space in \mathbb{R}^2 , is there any vector space in \mathbb{R}^2 , other than 0, other than the line passing through origin and the whole space.

(Refer Slide Time: 04:20)

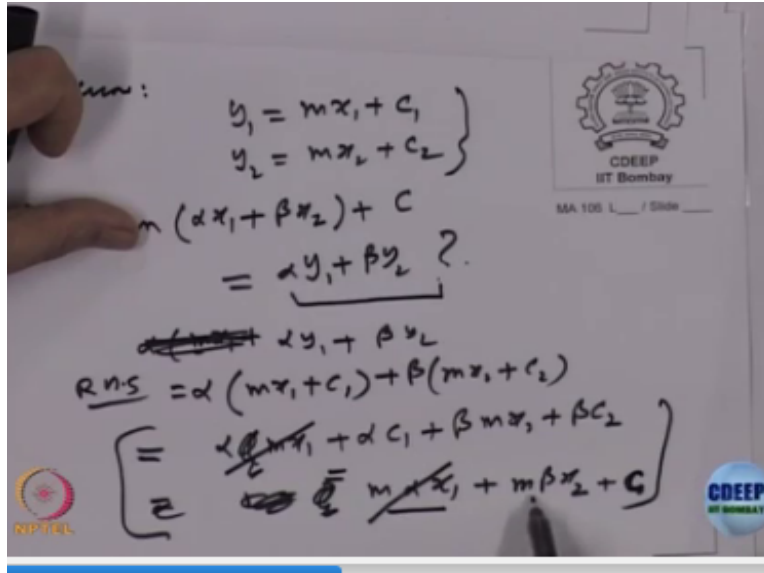

For example, let us look at this; this is an interesting example to consider, so look at a line not passing through origin, so L is the proper subset of \mathbb{R}^2 , a line not through origin, so question is; is it a vector space, so that is the question, so is it a vector space, so how do you describe a line as a set of vectors, so I can write this line L as; I want to write set of vectors in \mathbb{R}^2 , so how were been writing the vectors?

Normally, points in \mathbb{R}^2 are written as ordered pair; x, y you can write also has matrices, right, column vector x, y , whichever way, so let us write it as points for the time being, this x, y such that what is the relation between y and x , if they have to lie on a line, right, so $y =$ some $mx + c$, right for some m, c and if you want not so origin, then c should not be equal to $=0$, right, so that is all points in the plane which lie on the line are given by these 2 constants m and c .

So, I want to check, right, so whether if I take 2 points here, whether the combination, right, so as vectors what you will write; $x_1 y_1$, other vector would be $x_2 y_2$ on the line, so let belong to L and let us take α and β belonging to \mathbb{R} , then α of $x_1 y_1 + \beta$ of $x_2 y_2$, I want to check whether it belongs to L or not, what is that equal to; by our vector addition that is $= \alpha x_1 + \beta x_2$ and here it will be $\alpha y_1 + \beta y_2$, right, vector addition.

(Refer Slide Time: 06:59)

So, now let us go a step further and try to simplify this, what is the relation I know, so we know, what x_1, y_1, x_2, y_2 they belong to L , so what is $y_1 = mx_1 + c_1$, what is $y_2 = mx_2 + c_2$, right, so given this is the following true that means, $\alpha x_1 + \beta x_2$, right that is x squared, so whether can I say m times this $+ c = \alpha y_1 + \beta y_2$, is that okay. If this point; s_2 belong to L , then what should be the condition?

The y component should be $= mx$ component $+ c$, right, so can you say this is true then, right, so what is this, so this is α of $mx_1 + c_1$; I do not; do you think okay, so let me just ask you instead of saying, do you think this will be true because what is y_1 ; so, what is the right hand side? Let us look at the right hand side of this, what is that; α times y_1 , what is y_1 ? $x_1 + c_1 + \beta$ times y_2 that is $mx_2 + c_2$, so what is that $=$?

So that is α times mx_1 , okay α times $mx_1 + \alpha$ times $c_1 + \beta$ times $mx_2 + \beta$ times c_2 , so I can write this as, right, so I want whether this is $=$ this one; $m\alpha x_1$, so whether this is you want to know whether this is $=$ this $y_1, y_2 = m$ times α times, see this is y_1 , this $\alpha y_1 + \beta y_2$ that is $=$ this that is a right hand side is $=$ left hand side, what is the left hand side?

$\alpha mx_1 + m\beta x_2$, you know there is no; $m\alpha + m\beta x_2 + c_2$, so you want to know whether these 2 are equal or not, right, so do you think they are equal, where is c , yeah, so that is

c, right, see left hand side is $\alpha mx_1 + \beta mx_2 + c$, right, so what happens; αmx_1 , I can cancel out this, $\beta m \beta x_2$, I can cancel out this.

(Refer Slide Time: 10:20)

$$\left. \begin{aligned} &= \cancel{\alpha mx_1} + \cancel{\beta mx_2} + c \\ &= \cancel{\alpha mx_1} + \cancel{\beta mx_2} + c \\ &\alpha c_1 + \beta c_2 = c \quad \forall \alpha, \beta \end{aligned} \right\}$$

So that means this is asking for, is it true that $\alpha c_1 + \beta c_2 = c$, for every α , β , right then only left hand side will be = right hand side but that is not true for every α , β , for example, α you can choose 0, β you can choose 0, that means c should be 0 but c is fixed that is given to me, I cannot say it is 0, right, so this may not happen always. So that means what, so that is a contradiction, not possible always.

(Refer Slide Time: 11:07)

$$L = \{(x, y) \mid y = mx + c\}$$

$$c \neq 0$$

Then L is not vector space.

So, what does that mean? That means what is the conclusion; so the conclusion is that if I take $L = \{x, y\}$, where $y = mx + c$, $c \neq 0$, okay then L is not vector space, then it is not a vector space because if I take 2 elements and take scalar multiples of them and add that is not again in the same right, so that means in the plane every line through a origin is a vector space, every line which is not through a origin is not a vector space, right.

So, the question still remains, can you say these are the only subspaces or these are the only vector spaces in \mathbb{R}^2 , I cannot answer that question at present but that it is a true statement, so we will show later, right these are the only vector spaces in \mathbb{R}^2 either it should be a trivial that is 0 or it should be the whole space \mathbb{R}^2 or it should be a line passing through the origin, at present we have only shown these are vector spaces and no line not through a origin is a vector space.

But we will say these are the only ones evict later, okay, right, okay, so the line passing through the origin of slope and;

(Refer Slide Time: 12:40)

\mathbb{R}^n , vector spaces in \mathbb{R}^n

As usual we continue to think of elements of \mathbb{R}^n as $n \times 1$ columns.

Definition (Vector space)
 A subset $V \subseteq \mathbb{R}^n$ is called a vector space if

$$\mathbf{v}, \mathbf{w} \in V, a, b \in \mathbb{R} \implies a\mathbf{v} + b\mathbf{w} \in V.$$

Example:

- ① Let A be any $m \times n$ matrix.
 - $\mathcal{N}(A)$, the null space of A , is a vector space in \mathbb{R}^n ,
 - $A(\mathbb{R}^n) := \{A\mathbf{x} \mid \mathbf{x} \in \mathbb{R}^n\}$, called the **image space** or the **range** of A is a vector space in \mathbb{R}^m .
- ② Consider the set $L := \{\alpha\mathbf{X} \mid \mathbf{X} \in \mathbb{R}\}$. Clearly L is a vector space in \mathbb{R}^2 .
 Geometrically, L is the line in the plane passing through the origin, with slope α .

Note: that if $V \subseteq \mathbb{R}^n$ is a vector space, then $\mathbf{0} \in V$.

Prof. Indu K. Hans Department of Mathematics, IIT - Bombay

Now, this is an observation we said if a line does not pass through origin that is not a vector space in fact that is a property of every vector space that means if V is a vector space in \mathbb{R}^n , then the 0 vector should be inside it, why, why should 0 vector be inside every vector space, so what is the definition of a vector space? It says $\alpha V_1 + \beta V_2$ should belong to V for every V_1, V_2 in V and α, β scalar.

But who stops we are taking $\alpha = 0$ and $\beta = 0$, that means the 0 vector should be in V , right, $\alpha v_1 + \beta v_2$ should belong to V for every α, β and for every v_1, v_2 in V , in particular, if $\alpha = \beta = 0$, then what is $\alpha v_1 + \beta v_2$ that is 0, so 0 should belong to V , right, otherwise it is not true, right that property say so that means, it is a necessary condition for a subset V in \mathbb{R}^n to be a vector space that 0 must belong to it.

Otherwise, it cannot be a vector space, so that is what happened in the plane, no line which is passing through the origin, that means if a line is not passing through a origin, then zero vector is not part of it so, it cannot be a vector space and that is what we proved, checking actually, right, okay.

(Refer Slide Time: 14:21)

Linear span

A method to produce vector spaces is via *linear spans*.

Definition (linear combination and Linear span)

- Let $v_1, v_2, \dots, v_k \in \mathbb{R}^n$ and $c_1, c_2, \dots, c_k \in \mathbb{R}$. Then $c_1 v_1 + c_2 v_2 + \dots + c_k v_k$ is called a (finite) linear combination of v_1, v_2, \dots, v_k .
- Let $S \subset \mathbb{R}^n$. let

$$L(S) = \{c_1 v_1 + c_2 v_2 + \dots + c_k v_k \mid c_1, c_2, \dots, c_k \in \mathbb{R}; k \in \mathbb{N}\}.$$
 Then $L(S)$ is the set of all finite linear combinations of elements of the set S , and is called the linear span of S .

Theorem

$L(S)$ is a vector space in \mathbb{R}^n .

NPTEL Prof. Indu K. Rana Department of Mathematics, IIT Bombay

So, let us start with the some finite number of vectors in \mathbb{R}^n , okay, L scalars \mathbb{R} and look at this new vector $\alpha v_1 + \dots + \alpha c_1 v_1 + c_2 v_2 + \dots + c_k v_k$, so what I have done; I have scaled every vector $v_1/c_1, v_2/c_2$ and so on and taken a some of them, that is again a new vector right, so this thing; $c_1 v_1 + c_2 v_2 + \dots + c_k v_k$ is a new vector in \mathbb{R}^n , so such a vector will call as a finite linear combination of v_1, v_2, \dots, v_k , just a name.

Why finite? Because the number of vectors is finite, you can just call it as a linear combination, okay, but to stress that we are taking only finite number of them; we will get a finite linear

combination of these vectors. So, now comes a general definition, okay, so let us look at a set; the symbol has not come out S as a subset of \mathbb{R}^n , look at a subset S of \mathbb{R}^n , now what I can do?

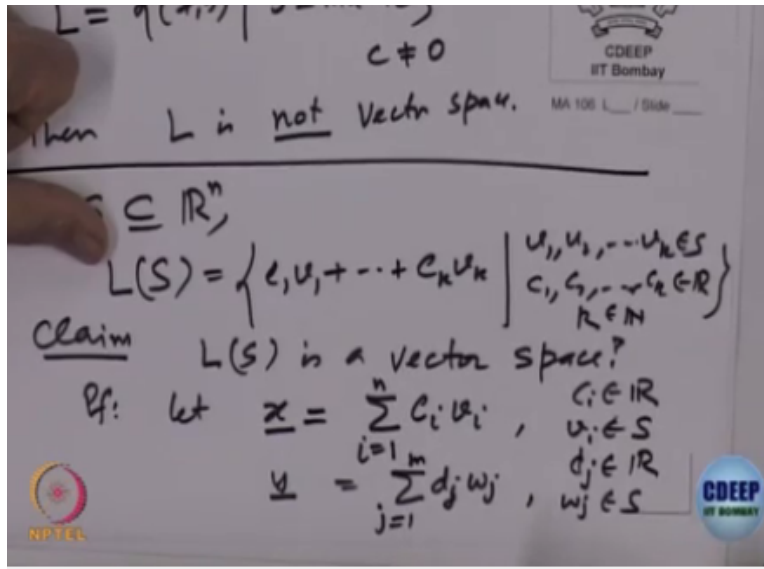

I can pick up any finite number of vectors from S and form a linear combination of those vectors, right, so I choose any vectors v_1, v_2, v_k in, right in S and look at scalars c_1, c_2, c_k in \mathbb{R} and form a ; so, where are these v_1, v_2, v_k , they are coming from right, from the set S , so that should have been written here, pickup v_1, v_2, v_k in S , scalars c_1, c_2, c_k in \mathbb{R} and look at this linear combination and make a set consisting of all these linear combinations called that as LS .

So, what is LS ? LS is a set of all finite linear combinations of vectors taken from S , right, is it clear, this k is not fix, k is not fixed, you can pick up only one vector, you can pick any 2, any 3, any 4, any finite number of them, form a linear combination by picking vectors finite number of them picking finite number of scalars making a linear combination. For all such possible linear combinations, right and call it as L of S .

For example, in that example in the plane, we took a fixed vector x_0 and multiply alpha by it, so we took all linear combinations of the only one vector as far as only single vector that was a line, so this is called a linear span; LS is called a linear span of the set S ; set S is the set of vectors, it may not have any property, right, you pickup elements from S , any finite number form a linear combination you get a new set, right of vectors that is called the linear span of set S , so that is ruled by L of S .

The theorem is LS is always a vector space as may be any set but LS is always a vector space, so let us check that why it is always a vector space, it is a simple proof but let us check it, okay, right.

(Refer Slide Time: 18:04)

So, S is a subset of \mathbb{R}^n , what is $L(S)$; $L(S)$ is $c_1 v_1 + c_k v_k$, right, where v_1, v_2, v_k 's, they belong to S and c_1, c_2, c_k 's they belong to \mathbb{R} and k is not fixed, so k is any natural number that also varies, is it clear what I am saying, we are not choosing only k vectors, we are choosing k is anything, I can choose 1 vector, I can choose 2 vector, 3 vectors, right, any finite number of vectors form a linear combination and put them in a box and that box is called L of S , right.

So, the claim is; L of S is a vector space, this is a vector space, so let us verify, so what we have to verify, right, so what is the proof, how do I verify this, to show it is a vector space, what I have to do? Take 2 elements of $L(S)$, take scalar multiples of them and add that should again be in $L(S)$, right. So, let us write, so let one element, let us call it as a vector x be $= \sum$, instead of writing dot, dot, dot, we will start using this notation, \sum , it is $c_i v_i$; $i = 1$ to some n , right, where c_i 's are real numbers, v_i 's are vectors in S , right.

Is it okay, let us take another vector y which is something, some other scalars $d_j w_j$; $d_j w_j$; j may be from 1 to m , we do not know from where to where, right, there may not be same vector chosen again, for y we would be choosing some other vectors, some other m number of them, so where d_j 's belong to \mathbb{R} and w_j 's belong to S , so that is what is given to us, so this what we have to check?

(Refer Slide Time: 20:45)

(5)

~~Sketch~~ Then for $\alpha, \beta \in \mathbb{R}$

$$\alpha \underline{x} + \beta \underline{y} = \alpha \left(\sum_{i=1}^n c_i \underline{u}_i \right) + \beta \left(\sum_{j=1}^m d_j \underline{w}_j \right)$$

$$= \sum_{i=1}^n \alpha c_i \underline{u}_i + \sum_{j=1}^m \beta d_j \underline{w}_j$$

$$\in L(S)$$

Hence $L(S)$ is a v.space.

So, check or let us write then, what is $\alpha x + \beta y$, then for α and β belonging to \mathbb{R} , I should add them and check it is again a linear combination right but what is this $=$; this α times $i = 1$ to n $c_i v_i + \beta$ times $j = 1$ to n $d_j w_j$, right but what is this; this is same as I can take α inside, so this $i = 1$ to n , $\alpha c_i v_i + \sum_{j=1}^m \beta d_j w_j$, is that okay but what is this?

That means I have chosen vectors; v_1, v_2, v_n up to v_n , I have chosen α vectors, right, so my new collection of vectors is probably $n + n$, each one is multiplied by some scalar and add it that is all, right, so is it clear that it belongs to LS, yes, it is again a linear combination; finite linear combination of elements from S that is all nothing more than that right, it is the matter of only writing, so these okay, so hence L of S is a vector space; L of S is a vector space.
