(Refer Slide Time: 00:26)

Functions  $f: D \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$

Suppose  $c \in \mathbb{R}^n$  s.t. every open ball at  $c$  intersects  $D$ .

( $c$  may  $\in D$  or may not be in  $D$ )

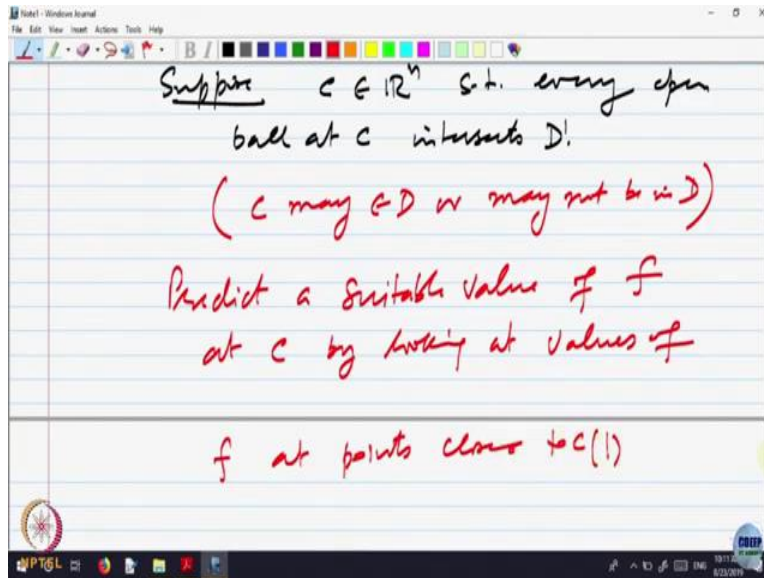

One way is

Functions  $f: D \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$

Suppose  $c \in \mathbb{R}^n$  s.t. every open ball at  $c$  intersects  $D$ .

( $c$  may  $\in D$  or may not be in  $D$ )

Predict a suitable value of  $f$  at  $c$  by looking at values of  $f$

So, now let us start looking at functions defined on real line. So, we are going to look at now next, looking at functions,  $f$  will be defined in some domain, some set of say  $\mathbb{R}^n$  to  $\mathbb{R}$ . Let us look at what I want to do to motivate the at let us look at the following situation. Suppose  $C$  is a point belonging to  $\mathbb{R}^n$  such that let me write every ball, every open ball at  $C$  intersects  $D$ .

So, this is I am assumption I am making so what does it mean, what I am saying is  $C$  is point so I think let me mention  $C$  may belong to  $D$  or may not be in  $D$ .  $f$  is function with the domain  $D$ , look at a point  $C$ , at point  $C$  may or may not be in the domain, function may or may not be defined we do not bother about it whether it is defined or not.

But the domain should have the property, there are points close to  $C$  in the domain where the function is defined. So, one way of ensuring that is every neighborhood of the point  $C$  intersects  $D$ . for example at  $C$  I can take a ball of radius  $1/n$  over  $n$  small or any epsilon that should intersect  $D$ . So, points close to  $C$  are in the domain that is the assumption I want to make. The function is defined at points as close to  $C$  as you want.

But we do not know whether function is defined at the point  $C$  or not. So, that is the situation I am having. The question is by looking at the values of the function at points close to  $C$  where it is defined, can I predict some suitable value for the function at the point  $C$ ? Is the question clear to everybody. So, let me repeat again, I want to look at the problem  $f$  is a function in some

domain, I am given and  $C$  is a point which may or may not be in the domain it may or may not be defined we forget whether it is defined or not.

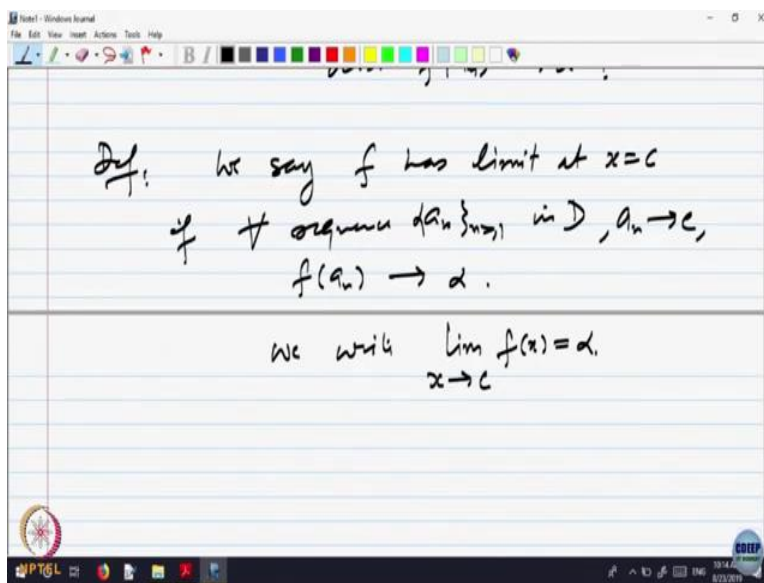

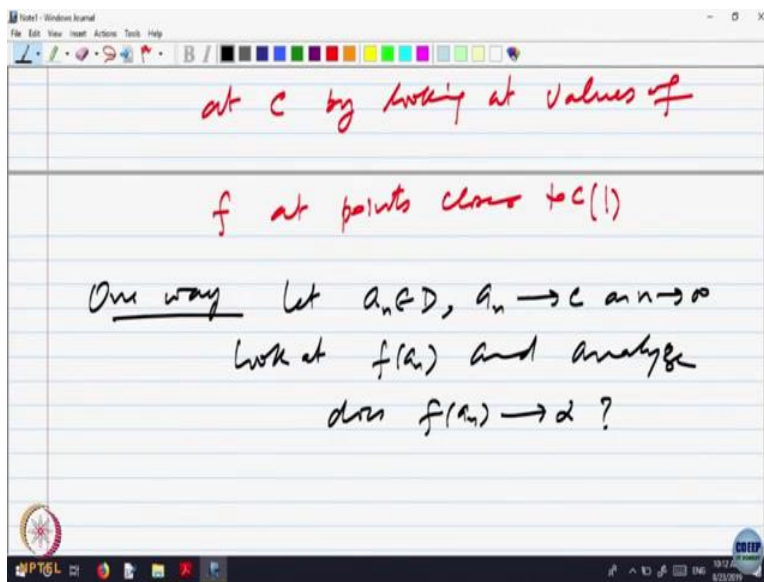

But positively the function is defined at points close to  $C$  how close, as close you want, function is defined. So, I know the behavior of the function at points close to  $C$ , that is idea I want to predict what could be the behavior of the function at the point  $C$  by looking at its behavior at points nearby.

So that is a prediction problem I being looking at, I am trying to predict a suitable value for the function at the point  $C$  by looking at its values at points close to it. So, what could be a way of doing that? One way could be that let us try to come closer and closer to  $C$  approach  $C$ . and close to  $C$  the function is defined, so look at the value of the function at points close to it, look at those images.

Those images if they are coming closer to something then that could be a suitable value for the function to be predicted. Is it a natural thing to do? Is it ok, intuitively very clear? So, how do I approach a point in  $D$ , I can take a sequence in  $D$  which is converging to  $C$ , then the points of the sequence will be coming close to  $C$  as close as you want, is it ok.

So, that is why I have put the condition that close to  $C$  every neighborhood must intersect. So, there are sequences which are coming to  $C$ . So, let us look at a sequence one way is, so I have not written what is the problem, so let me write the problem. So, the problem I am looking at is predict a suitable value of  $f$  at  $C$  by looking at values of  $f$  at points close to  $C$ . So, that is what we are trying to do.

(Refer Slide Time: 06:15)

So, one way could be, so one way is let  $a_n$  belong to  $D$  and  $a_n$  come to  $C$  as  $n$  goes to infinity. Look at, I am trying to predict a value or the function at the point  $C$  at a point close  $a_n$ , this is the value. So, look and analyze, does  $f$  of  $a_n$  come closer to a value, what is the meaning of that? Converges to some value  $\alpha$ . So, what we are saying is, look at sequences in the domain which converges to  $C$  and look at the image sequence for those points  $f$  of  $a_n$ .

If they converge to some value then that value could be a suitable value. As I am approaching the point  $C$ , I am approaching the value  $\alpha$ . But it should not happen one sequence  $a_n$  is

converging to the  $C$  and  $B_n$  is also converging but  $f$  of an actually converges to some value and  $f$  of  $B_n$  converging to some other value.

Then will be in a problem which value is a suitable value. So, we should have for every sequence an converging to the point  $C$ ,  $f$  of an should converge to the same value. Then that value will be a suitable value for the function at that point  $C$ . So, we are trying to predict by looking at the behavior at nearby points, we are not concerned what is a value at the point  $C$ , is it ok, clear the problem?

And if that happens one says the function has a limit at the point  $C$ . So, let us put a definition, we say  $f$  has limit at say  $x$  is equal  $C$  if for every sequence  $a_n$  in the domain an converging to  $C$ .  $f$  of  $a_n$  converges to  $\alpha$ . We write  $\lim_{x \rightarrow C} f(x) = \alpha$ . So, keep in mind limit is something to which the function is approaching as you approach the point in the domain.

So, naturally conditions are there should be a sequence at least one sequence converging to that point in the domain. Otherwise what are you going to predict, you are not going to predict anything. So, close to  $C$  there should be points in the domain as close as you want so that you can analyze the behavior of the function at points close to  $C$ .

And once the data is given I look at the behavior of the image sequences, if all the image sequences converges to the same value then we say that is a value the function should take and we say mathematically that function has a limit as  $x$  goes to  $C$ , clearly function need not to be defined at that point.

It is a suitable value for the function by looking at its behavior nearby. That is a way we should understand limit of a sequence and that is why we have understood for example for a sequence what was the limit, for a sequence  $a_n$  the limit,  $a_n$  need to be equal to  $C$  at all only they are coming closer and closer that was then sometime they may be equal to the value that does not matter.

But we do not bother about whether elements of the sequence are taking that value of where it is going to converge or not. Same for the function the limit is something which we want to predict a suitable value where the function is coming closer and closer to some value. As in the domain you come closer to the value  $C$  and that closeness mathematically is measured by a sequence in

the domain converging to  $C$  that is an is converging to  $C$ , so an are coming closer to  $C$ ,  $f$  of an are coming close to some value alpha whatever be.

(Refer Slide Time: 11:42)

So, if you want to look at a picture in  $R^n$  say  $R$ , so this is the domain and here is the value alpha, so where any point. So, for example the point  $C$  could be here. So, if you take a sequence  $x_n$  which is converging into  $C$  so look at  $f$  of  $x_n$ , it will be here, it could be here, but they are all coming closer to the value alpha.

And you see in  $R^n$  there could be many ways of approaching  $C$ , there could be many paths. But whatever way whichever way  $x_n$  is converging, we know how to  $x_n$  converge, absolute value of or the magnitude of  $x_n$  minus  $C$  goes to 0 we know that, the distance goes to 0. So, path is not important, it is the closeness which is important and incase the function is defined at the point  $C$ .

Supposing it so happens that the point  $C$  is in the domain that means the function is given some value. That may or may not be same as the value that we are trying to predict. So, if the value we are predicting for the function at the point  $C$  by looking at its behavior at nearby points happens to be same as the value or that function at that point  $C$  then it is natural to say there is a continuity in the behavior of the function.

Whatever we are trying to predict function behaves nicely there is a continuity in this behavior. So, that gives us a notion of what is called continuity of a function at a point if the value we are predicting, is the actual value taken by the function. So, continuity of the function at a point

means the point is in the domain that means  $f$  of  $C$  is defined and for every sequence  $x_n$  converging to  $C$ , the limit is equal to  $f$  of  $C$ .

So, value predicted is the actual value taken that is how we should understand what is called the continuity of a function at a point. All of you have done this limits and continuity in your previous courses but just this perspective you should keep in mind.

(Refer Slide Time: 14:16)

def.  $f: D \subseteq \mathbb{R}^n \rightarrow \mathbb{R}$   
 $C \in D$ .  $f$  is continuous at  $x=C$   
if  $\lim_{x \rightarrow C} f(x) = f(C)$ .

---

$f \circ g$  is cont at  $x=C$   
 $(f \circ g)(C)$  is defined

$(f \circ g)(C)$  is defined  
let  $x_n \rightarrow C$

---

$(f \circ g)(x_n) = f(g(x_n)) \rightarrow (f \circ g)(C)$

§

So, let me define, so limit we have defined. So, let us define what is called, so definition  $f$  defined in a domain in  $\mathbb{R}^n$  to  $\mathbb{R}$ ,  $C$  belongs to  $D$ ,  $f$  is continuous at  $x$  is equal to  $C$  if limit  $x$  going

to point is  $C$ ,  $f$  of  $x$  is equal to  $x$  and is the value or the function at that point  $f$  of  $C$ . The value predicted is the actual value taken. So, that is continuity and now you all must have done this kind of theorems namely if the limit. You see now what we are looking at, we are looking at some property of functions now.

So, our aim... our domain of attraction or investigation is the class or functions defined on real lines or  $\mathbb{R}^n$ . Now you can add functions. So, what are the operations possible on this class, you can add functions, you can multiply functions, you can divide functions, you can compose functions.

And the theorems are over the limits which we have already done. If  $f$  has a limit at a point  $C$ ,  $g$  has a limit at a point  $C$  then  $f$  plus  $g$  has a limit at the point  $C$  and the limit is equal to sum of the limits. Similarly difference product, you can do also coefficient, you have to keep in mind limit of coefficient is not equal to 0 as in sequences we have done that.

So, those are called algebra of limits, limit of the sum is equal to sum of the limit, limit of the product is equal to product of limits and so on. I am just recalling you what you what you have might have already done. So, translate this for continues functions. If  $f$  and  $g$  are continues,  $f$  plus  $g$  is continues because the limit is equal to sum of the limits. Product of continues functions is continues.

Composition of composite functions in continues. Let me just indicate. So, supposing  $f$  is a function and such that and  $g$  is another function that  $f$  composite  $g$  is defined on some domain. I want to say that is continues at  $x$  is equal to  $C$ . So,  $f$  compose with  $g$  at  $C$  is defined. So, that is assumption, for composite of function is not always that I have composite  $g$  is defined whenever the range of  $g$  is in the domain of  $f$  it will be defined.

To show continuity let  $x_n$  converge to  $C$ , we want to analyze  $f$  composite  $g$  of  $x_n$ , what is that equal to by definition? It is  $f$  of  $g$  of  $x_n$ , and where is  $x_n$  converging to  $C$ . But I should have now  $g$  of  $x_n$  converging somewhere otherwise I cannot say anything. So, condition is if  $f$  composite  $g$  is defined and  $g$  is continuous at  $C$  where domain and  $f$  is continuous at the  $g$  of  $x_n$  then this is continuous and this will converge to of composite  $g$  of  $C$ .

So, appropriately you can out conditions,  $f$  composite  $g$ , so what should happen? I am looking at the point  $C$  limit at the point  $C$ . So, first of all... composite  $g$  should be defined, first  $g$  is operating and then  $f$  is operating. If  $x_n$  is converging to  $C$ , look at the image that is  $g$  of  $x_n$  that should converge to  $g$  of  $C$ .

So,  $g$  of  $x_n$  is converging to  $g$  of  $C$ ,  $f$  is defined there and if  $f$  is continuous at the point  $g$  of  $C$  then  $f$  composite  $g$  will converge to  $f$  composite  $g$  at the point  $C$ , is that ok. So, those are the appropriate conditions that you should put by looking at what is to be done. So, conditions are not put just for the sake of being happy, it is because each one is required at some stage, is that clear to everybody what I am saying, all of you have done this but I am just revising and trying to make you understand, how you should understand something.

(Refer Slide Time: 19:56)

The image shows a digital whiteboard with handwritten mathematical notes. At the top, the word "Properties" is written and underlined. Below it, a theorem is stated: "① Let  $f: I \rightarrow \mathbb{R}$  be continuous. If  $I$  is an interval  $\Rightarrow f(I)$  is an interval?". Underneath, the word "Proof:-" is written, followed by "I interval" and " $f(I)$  is an interval?". The next line says "Let  $\alpha \in f(I), \beta \in f(I)$ " and the final line says "and  $\alpha < \beta$ ". The whiteboard interface includes a menu bar (File, Edit, View, Insert, Actions, Tools, Help), a toolbar with various drawing tools, and a Windows taskbar at the bottom with several icons and a system clock showing 10:00 AM on 10/10/2020.

So, we will not spend time on composition of, on this properties of continuous function and so on. What we were going to look at is, some properties of continuous function. So, let me look at algebra of limits, algebra of continues functions as we are assuming, that you have all gone through and if you are not gone through or you would like to be more comfortable do it again, look at the proofs of limit of the sum is equal to sum of the limit and so on.

Be happy so that you understand, be I think is other way around. Understand and be happy, you will be always be happy if you understand. So, properties so what we were going to look at is, we are going look at properties of continuous functions, vis a vis special properties of subsets of real line.

For example if the function is defined on an interval, domain is a interval. What can I say about the range or the function, can I say it is a interval? If the domain is the interval can I say the range is interval or another property if the domain is a closed bounded interval can I say the range should be a close bounded interval. So, such kind of properties we want to look at of continuous functions.

So, continues functions, vis a vis special properties of subset of the domain. So, the first one is let  $f$  be a function defined on  $I$  to  $\mathbb{R}$ , where  $f$  is continuous why write where be, so let  $f$  be continuous such that be continuous let me just write there is no such that meaning if  $I$  is an interval implies  $f$  of  $I$  is an interval.

I want to look at this property. So, let us see how does the proof work, I want to look at, so I interval,  $f$  of  $I$  is an interval that is a question we are looking at. How do you approve  $f$  of  $I$  is an interval? How can I prove? The only way we know is take two points in that set, take a point in between that is you were also be in that set. So, let us check  $\alpha$  belong to  $f$  of  $I$ ,  $\beta$  belong to  $f$  of  $I$  and either  $\alpha$  will be less than  $\beta$  or, so let us write and  $\alpha$  less than  $\beta$ .

Let  $\alpha$  less than  $\gamma$  less than  $\beta$ . Take a point in between, we are taken two points in  $f$  of  $I$  and we are looking at a point in between, claim we want to analyze  $\gamma$  belongs to  $f$  of  $I$ , now what is the meaning of saying  $\alpha$  belongs to  $f$  of  $I$  means what, trying to understand that means  $\alpha$  is in the range of the function.

You see what we are trying to analyze the range and we know only something about the domain that is a interval. So, somehow I have to shift my attention to the domain and use the fact that domain is a interval. So, the proof has to be in such a way, I have to drive my proof in such a way that it goes to the domain somehow and then use that fact.

I can do something there only, so how do I go to the domain, it belong implies there is some  $x$  belonging to  $I$  such that  $f$  of  $x$  is equal to  $\alpha$ ,  $\beta$  belongs to  $f$  of  $I$  that is same as saying there exists a point so let us call it  $x_1$  and call it  $f$  of  $x_2$  there is a point  $x_2$  where the value  $\beta$  is equal to  $\beta$ .

At a point  $x_1$  because it is  $\alpha$  is in the range so some value, some point  $x_1$  should be mapped to  $\alpha$  other point  $x_2$  should be mapped to  $\beta$ . Now  $x_1, x_2$  both are in  $I$ , so now the idea is, so let me draw a picture probably that we, I am going to give you a picture which is only sort of real line. So, here is the domain, here is the function, here is  $x_1$  here is  $x_2$ , here is the value  $\alpha$  and here is the value  $\beta$  and here is the value and  $\gamma$  is in between.

So, here is the point  $\gamma$ . Now, I can directly work with  $\alpha, \beta, \gamma$  and so on straightly proof will be understandable more, does not matter. So, let me I think probably do it straight away here itself, let me write, so draw this line. So, what I want to show, aim is to show that  $\gamma$  belongs to  $f$  of  $I$  that means what, there is a point in the domain where the value  $\gamma$  is taken, is it ok.

So, we want to show there is, this is the value  $\gamma$  and what is geometrically if you look at what is the meaning of saying that the function will take the value  $\gamma$  somewhere. I am institutive notion of a function, if you will have the picture of the function, what does it mean? What is the picture of a function?

You all done calculus, what is the picture of a function, that is the graph of the function, graph is the picture or the function and if you want to say that the value  $\gamma$  is taken somewhere by the function that means the graph must intersect that line somewhere that is a geometric way of saying.

So, you want somewhere the graph should cut somewhere at a point, that is a point we are looking at, that is the point we are looking at. So, how do I capture that point that is the question? I want to capture this point in the domain. So, how do I capture it that is the question? So, now you see one way of capturing this point is, see look at this point this value  $x_1$ .

So, what I can do is I can start looking at points bigger than  $x_1$  where the value is this value  $\alpha$  is less than  $\gamma$ . So, look at all the points where the value is less than  $\gamma$ , and try to look at the largest of these values in the domain. See I am going to look at the domain only, is it ok.

So, look at the largest so possibly that value, so at this point the value still remains below  $\gamma$ , below the line, at the point next also it remains below  $\gamma$ . So, look at the largest possible value in the domain bigger than  $x_1$  where the graph stays below that line. So, if I have the largest value that means after that it will attached to crossover otherwise it will not be the largest. So, that is one way of analyzing the proof. So, what should be we do, so the proof starts by looking at.

(Refer Slide Time: 29:40)

$A = \{x \in [x_1, x_2] \mid f(x) < \gamma\}$   
 N/A  $x_1 \in A \Rightarrow A \neq \emptyset$   
 $A$  is bounded above.  
 $\Rightarrow c := \text{lub}(A)$  exists  
N/A

$A$  is bounded above.  
 $\Rightarrow c := \text{lub}(A)$  exists  
N/A  $\Rightarrow f(c) \leq \gamma$ ! — ①  
 $\left[ \begin{array}{l} \exists a_n \in A, a_n \rightarrow c \\ \Rightarrow f(a_n) \rightarrow f(c), f(a_n) < \gamma \\ \Rightarrow f(c) \leq \gamma \end{array} \right]$   
 Hence  $x_1 \leq c \leq x_2$   
 Can  $c = x_2$ ? No  
 $\therefore f(x_2) = \beta > \gamma$

So, let us look at the set A, all x belonging to this  $x_1, x_2$  such that  $f(x) < \gamma$  is it ok. So note,  $x_1$  belongs to A, because the value at  $x_1$  is  $\alpha$ . So, A is non empty I am trying to look at the largest value, I have to ensure the largest value exist, so how do I ensure the largest value exist? The only way I know is lub property of real line.

So,  $x_1$  belongs to A implying A is non empty, A is bounded above, why it is bounded above, because it is inside  $x_1, x_2$ . We are choosing points between  $x_1$  and  $x_2$  only so it is bounded above. So, implies  $\gamma = \text{lub}$ , not  $\gamma$  something else I should write because  $\gamma$  I already used so let us write C equal to lub of A exists. Now where you see note, what is

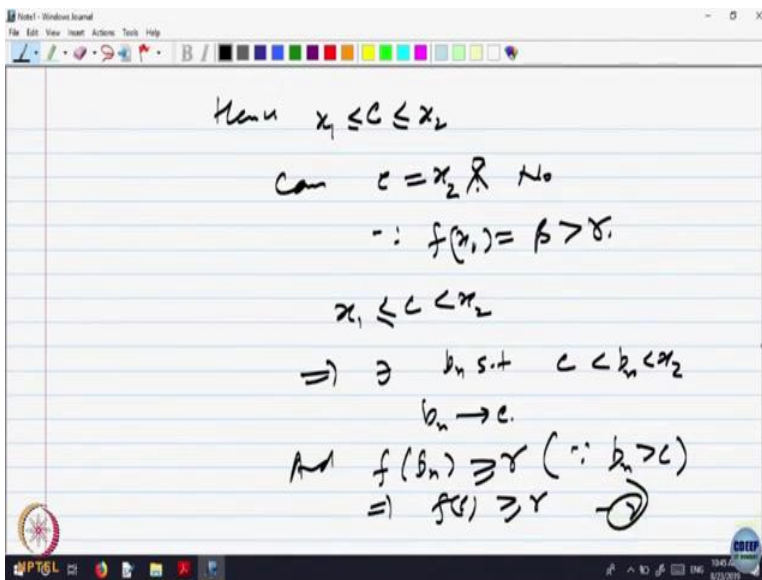

the value of the so I have taken and I have gotten a point C which is lub of these points, you have the values less than gamma.

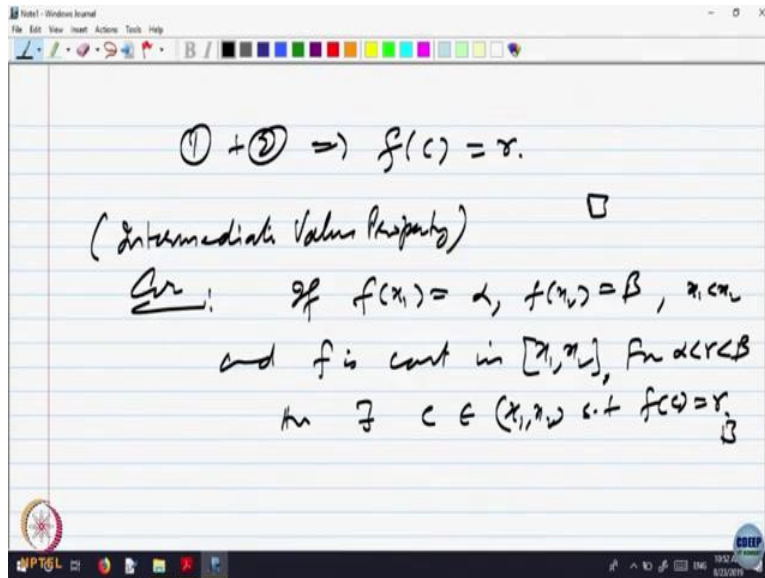

My aim is to show the value at the C is equal to gamma, value at the point C is equal to gamma. So, first of all look at note C is lub of something so I am saying this implies f of C is less than or equal to gamma. Why is that C is lub of a set A, in the lub of set A there must be a sequence in A converging to lub, there must be a sequence converging in lub.

So, I am not writing the proof I am just try to understand what I am saying, C is lub so that means what, that means there must be a sequence in A converging to lub, we have already seen that, C minus 1 over N cannot be there must be a point all that we have done. So, there is a sequence in A converging to C.

So, there is a sequence, so what is the value at that point or the sequence. So, what is the value at that points or the sequence they are in A. So, f of C is f of that element of the sequences is less than or equal to less than gamma, f is continues, so image must have the property so let me write here, their exist a sequence an belonging to A, an converging to C implies f of an converging to f of C because of continuity, f of an because it belongs A is less than or equal to gamma implies f of C is less than or equal to gamma that is a proof. So, I used continuity here.

(Refer Slide Time: 33:42)

So, now what is the possibility. So, hence so what we were saying is that point C is bigger than or equal to  $x_1$ , is less than or equal to  $x_2$ . It is bigger than or less than because  $x_2$  is a upper bound and this is lub. So, it has to be less than or equal to  $x_2$ . Now, the question is can C be equal to  $x_2$ ?

What is the value if C is equal to  $x_2$  what is the value at  $x_2$ . That is beta which is bigger than gamma that cannot happen because just now I said  $f$  of C is less than or equal to gamma. So, this C cannot be equal to  $x_2$ , so let us write no because  $f$  of  $x_2$  is equal to beta is bigger than gamma.

So,  $x_1$  less than C less than  $x_2$ , it has to be but still we want to show that  $f$  of C is equal to gamma, it is less than or equal to gamma. If I can show it is also bigger than or equal to gamma we are through. But this implies, there is a sequence  $b_n$  such that C is less than  $b_n$  and less than  $x_2$  and  $b_n$  converging to C, is that ok.

Because if C is less than  $x_2$  then there is a gap in between I can always have a sequence coming to C from that side. And where are these  $b_n$  and what can say  $f$  of  $b_n$ ,  $b_n$  is on the right side of alpha which is the supremum, where the value of the function is less than, so it has to be bigger than or equal to, that is only possibility. Alpha is the lub of all points in  $x_1$   $x_2$  where the value is strictly less than gamma.

So, something bigger than lub at that point the value has to be bigger than or equal to gamma, is that ok. Because  $b_n$  bigger than C, is that ok or not ok here look at the graph you will understand

it better. So, here you see  $C$  and less than  $x_2$  so there is  $b_1$ , and so on,  $b_n$  converging to  $C$ . What can be the value at this point, it has to be bigger because what is  $C$ ,  $C$  is the least upper bound of all those points where the value is less than  $\gamma$ .

So, something bigger than that least upper bound the value has to be bigger than or equal to  $\gamma$ . So, these are points here, in this file. So, that means what so implies  $f$  of  $C$  by continuity again is bigger than or equal to  $\gamma$  because  $f$  is continuous. Each element of the sequence  $b$  and  $f$  of  $b_n$  is bigger than  $\gamma$ ,  $b_n$  is converging to  $C$  so where does  $f$  of  $b$  and converge.

It converges to  $f$  of  $C$  by continuity, each  $b_n$  is bigger than or equal to  $\gamma$  so limit has to be also bigger than or equal to  $\gamma$ . So, this is second and the first one was it is less than or equal to. So, this is one and you can call this as two if you like. One into imply  $f$  of  $\gamma$  is equal to,  $f$  of  $C$  is equal to  $\gamma$  sorry not 0,  $f$  of  $C$  is equal to  $\gamma$  and that finishes. We are not doing anything surprising very naturally, what we are saying is here and if you look at the picture at this point the value is  $\alpha$ .

(Refer Slide Time: 38:30)

So, let me start travelling along this route, go on moving till you remain below the graph and look at the largest value of this where you stay below. That must be the point where you crossover, that must be the point that you crossover. So, written mathematically look at all the points in  $x_1$   $x_2$  where the value  $f$  of  $x$  is less than  $\gamma$ , that is a non empty set less than or equal to  $\gamma$ , yes that is non empty set.

It is bounded above by  $x_2$  so it must have a least upper bound and that least upper bound is the required one. Because everything on the right hand side will be bigger than or equal to, here it is less than or equal to that all it is equal to gamma. So, that is one way of proving that if a function takes two values alpha and beta then it takes every value in between.

Another way of saying the same result what we have shown, if  $I$  is a interval  $f$  of  $I$  is a interval, but what is meaning of saying. If  $I$  is interval, alpha and beta are two values then every value in between also has taken that is what are showing. So, this theorem can also be interpreted as saying for a continues function if two values are taken alpha and beta then every value in between also must be taken at some point.

So, in that way it goes by the name of intermediate value property for continues functions. So, the proof that image of a interval is interval also gives you what is called intermediate value property, it is same. So, corollary if will... what is the doubt, where is  $b_n$ ? It is on the right side,  $b_n$  is on the right side of  $C$  and what is  $C$ ,  $b_n$  is not belong to  $A$ , who said  $b_n$  belong to  $A$   $b_n$  is the set of those points in a where  $f$  of  $x$  is less than gamma.

(Refer Slide Time: 41:17)

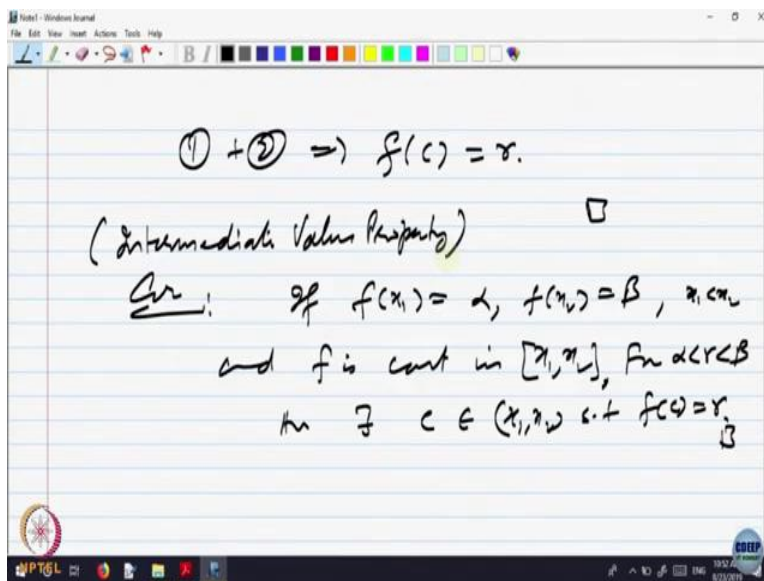

$$A = \{x \in [x_1, x_2] \mid f(x) < \gamma\}$$
 N/A  $x_1 \in A \Rightarrow A \neq \emptyset$   
 $x$  is bounded above.  
 $\Rightarrow c := \text{lub}(A)$  exists  
 N/A  $\Rightarrow f(c) \leq \gamma. ! \text{--- (1)}$

It is not all  $x_1$   $x_2$ . Look at the definition of  $A$ , what is  $A$ ?  $x$  belonging to  $x$  such that  $f$  of  $x$ . So, for all points of  $A$   $f$  of  $x$  is less than gamma and we are taken the supremum of it, supremum of  $A$  is alpha, so any point on the right side of alpha cannot be an element in  $A$ , because alpha is the least upper bound of  $A$ .

So, if it is not in A or any point  $f$  of  $x$  is less than  $\gamma$ . So, it is not it is outside that means what, the value should be bigger than or equal to  $\gamma$ . So, for all point on the right side of C the value is bigger than or equal to  $\gamma$  only we have to ensure that there are points on the right side and for that C cannot be equal to  $x_2$ .

Because  $f$  at C is less than or equal to  $\gamma$  we have just now shown,  $f$  of C is less than or equal to  $\gamma$  so C cannot be equal to  $x_2$  because the value at  $x_2$  is  $\beta$  which is bigger than  $\gamma$ . So, there has to be a gap in between that means C has to be strictly less than  $x_2$ . So, it is interval in between. So, take any sequence converging and that does the job.

(Refer Slide Time: 42:57)

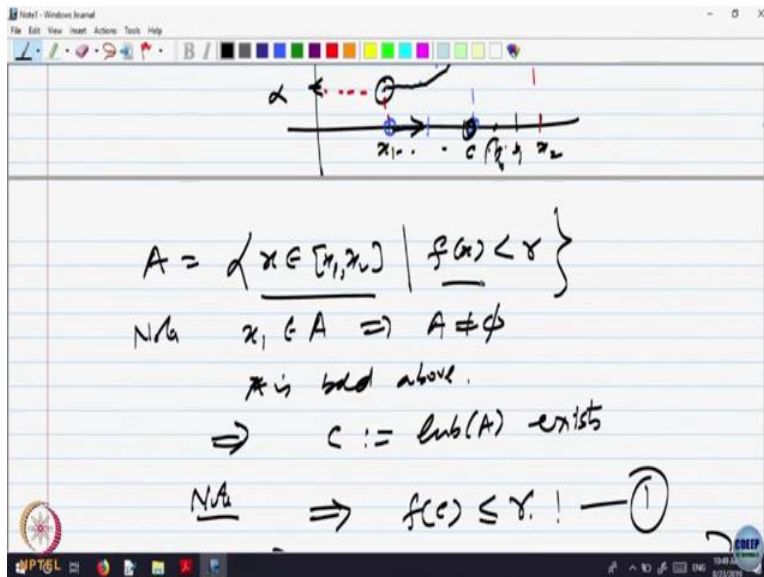

So, I was writing another way of this or a consequence of this whichever way you like. If  $f$  of  $x_1$  is equal to  $\alpha$ ,  $f$  of  $x_2$  is equal to  $\beta$  and  $f$  is continuous in  $[x_1, x_2]$ . I am not saying  $x_1$  should be less than it could be other way around,  $x_2$  could be less than  $x_1$ . So, let us say  $x_1$  less than  $x_2$  or it will be other way around then there is a point C belonging to  $x_1, x_2$ . Say that  $f$  of C and  $\gamma$  is graph continuous for  $\alpha$  less than  $\gamma$  less than  $\beta$  there is a point C such that  $f$  of C is equal to  $\gamma$ .

So, if a continuous function takes two values  $\alpha$  and  $\beta$  it must take every value in between. So, that is what is called intermediate value property. This is very useful result, for example at some you want to locate where does the graph of a function, let us first interpret this

geometrically, geometrically they says if you are here and you want to go here, there is a value at alpha, there is value at beta.

(Refer Slide Time: 44:20)

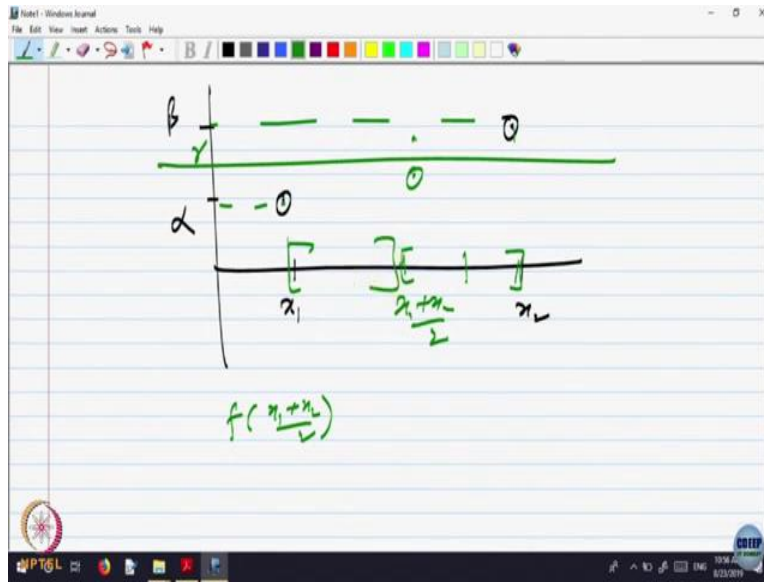

If you want to go and every value must be taken, this value will not be taken if you say that you go up to here and then you start your graph somewhere else. So, geometrically saying intermediate value property holds for continues function means the graph of the function has no breaks.

That is a geometric interpretive of this, so continuity of a function at a point means if you start somewhere and domain is a interval then and you end somewhere, then once you start drawing the graph you should not life your pen or pencil whatever you are doing to draw the graph, you should continuously go on doing.

There is no break in the graph of the function, this is why it is important in calculus when you want to get a picture of the function there is a first tool which gives you a picture of the function. Namely continuity implies there is no break in the graph of the function.

(Refer Slide Time: 45:46)

So, let us look at some, here is another way of proving this that is interesting. So, let us just look at  $x_1$ , at  $x_2$  here the value is some alpha here the value is something beta, and here is gamma in between. See we are trying to locate a point in between  $x_1$  and  $x_2$  where things crossover. So, another very intuitive way of doing this is the following, at  $x_1$  the value is alpha and  $x_2$  the value is beta.

What I can try to do is look at the midpoint of this and look at the value at the midpoint. So, look at  $f$  of  $x_1$  plus  $x_2$  by 2, what are the possibilities. Either it is equal to gamma that is a place where actually the function crosses one possibility, you are very lucky or it is below or it is above. Only three possibilities if it is cutting at that point the line gamma then we are through, if not let us assume it is below.

So, let us assume the value here that is still below, now value at  $x_2$  is above. So, now let us only concentrate only in this part of the graph. The original one at  $x_1$  would have below,  $x_2$  it was above. Now, I have shrunk my vision, I know I do forget about everything else, look at only the midpoint and  $x_2$  at the midpoint the value is below, at  $x_2$  value is above.

So, you see now I am trying to capture that point kind of thing. Now again I will look at the midpoint of that again possibility same either I hit the jackpot, I get the value or it is below or it is above. So, if it is below I continue that process and go on shrinking. Now, if at this stage, the value is above, supposing at this stage I assume the value is below.

Supposing it was above then I will consider only on this part. So, what I am doing is at  $x_1$ ,  $x_2$ .  $x_1$  the value is less  $x_2$  the value is bigger, cut it into half and keep only that half at one end point the value is less, the other end point the value is more again cut it into half and see which one is working.

So, go on shrinking this interval. At one end point the value is less, the value is more so what you get? You get an nested sequence of intervals. Such that at the left end point the value is less at the right end point the value is more and the intersection of all of them has to be a single point. What will be the value at the single point?

It has to be equal to  $\gamma$  because if I look at the left hand points, it should be less than or equal to  $\gamma$ , if you look at the right end points it should be bigger so they have to be same. So, this is called the bisection method of capturing a point, making it smaller and so you can write down the, I am not writing the proof it is second proof, you can try to write out the proof yourself.

The basically the idea is  $x_1$ ,  $x_2$  at  $x_1$  the value is less,  $x_2$  the value is bigger cut it into half either this half or this half will have the same property again at the left end point the value will be less, at the right hand point the value will be more, go on doing it if you do not hit the jackpot in between then eventually you should capture that point.
