

## Theorem 5

► Let  $u(s) = \sum_k a_k s^k$ . Then  $\phi(t; s)$  satisfies:

1.

$$\frac{\partial \phi(t; s)}{\partial t} = \frac{\partial \phi(t; s)}{\partial s} u(s)$$

2.

$$\frac{\partial \phi(t; s)}{\partial t} = u(\phi(t; s))$$

with the initial condition

$$\phi(0; s) = \sum_j P_{ij}(0) s^j = s$$

Now we will move into the theorem 5 which discuss the differential equation corresponding to the probability generating function for  $P_{ij}$  of  $t$ . Let that  $u$  of  $s$  is equal to summation  $a_k s^k$  summation over  $k$ . Then the probability generating function for  $P_{ij}$  of  $t$  satisfies partial derivative of  $\phi$  of  $t, s$  with respect to  $t$  is equal to partial derivative of the  $\phi$  of  $t, s$  with respect to  $s$  multiplied  $u$  and partial derivative of  $\phi$  of  $t, s$  with respect to  $t$  is same as  $u$  of  $\phi$  of  $t, s$  with the initial condition  $\phi$  of  $0, s$  is same as a summation over  $j$   $P_{ij}$  of  $0 s^j$  but that is nothing but  $s$ . So the theorem 5 gives the partial differential equation and the ordinary differential equation satisfied by the partial by probability generating function of a  $P_{ij}$  of  $t$ .

## Theorem 5 . . .

► **Proof:** We have

$$\begin{aligned}
 \phi(h; s) &= \sum_j P_{ij}(h) s^j \\
 &= \sum_j (\delta_{1j} + a_j h + o(h)) s^j \\
 &= s + h \sum_j a_j s^j + o(h) \\
 &= s + hu(s) + o(h)
 \end{aligned}$$

► Now

$$\phi(t + h; s) = \phi(t; \phi(h; s)) = \phi(t; s + hu(s) + o(h))$$

► By Taylor's theorem, we expand the right-hand side with respect to the second variable

$$\phi(t + h; s) = \phi(t; s) + \frac{\partial \phi(t; s)}{\partial s} hu(s) + o(h)$$

Let us see the proof. We start with  $\psi(h; s)$ ,  $\psi(h; s)$  that is nothing but the summation over  $j$   $P_{ij}(h) s^j$ ; substitute the  $P_{ij}(h)$  and simplify you will get the first term will be  $s$ . The second term will be  $h$  times summation over  $j$   $a_j s^j$  the second term will be order of  $h$ . You know that  $u(s)$  is same as summation over  $j$   $a_j s^j$  therefore the probability generating function for  $P_{ij}(h; s)$  that is nothing but  $s + hu(s) + o(h)$ . We know that by the theorem four,  $\psi(t + h; s)$  will be  $\psi(t; \psi(h; s))$ . So substitute  $\psi(h; s)$  with  $s + hu(s) + o(h)$  therefore this will be  $\psi(t; s + hu(s) + o(h))$ . By Taylor's theorem we expand the right hand side with respect to the second variable. Therefore, the right hand side will be  $\psi(t; s)$ . The second term will be partial derivative of  $\psi$  with respect to  $s$  times  $h$  of  $u(s)$  plus order of  $h$ . All the other term vanishes throughout divide by  $h$  and take  $\psi(t; s)$  in the left side.

## Theorem 5 ...

- ▶ Hence

$$\frac{\phi(t+h; s) - \phi(t; s)}{h} = \frac{\partial \phi(t; s)}{\partial s} u(s) + \frac{o(h)}{h}$$

- ▶ Taking  $h \rightarrow 0^+$ , we get

$$\frac{\partial \phi(t; s)}{\partial t} = \frac{\partial \phi(t; s)}{\partial s} u(s)$$

- ▶ This is a partial differential equation for the function of two variables  $\phi(t; s)$  with the initial condition

$$\phi(0; s) = \sum_j P_{ij}(0) s^j = s$$

Therefore, the left-hand side becomes  $\psi(t+h, s) - \psi(t, s)$  divided by  $h$  whereas in the right hand side will be partial derivative of  $\psi$  with respect to  $s$  times  $u(s)$  plus  $o(h)$  divided by  $h$ . Taking  $h \rightarrow 0^+$  we get the partial differential equation  $\frac{\partial \psi}{\partial t} = \frac{\partial \psi}{\partial s} u(s)$ . This is a partial differential equation for the function of two variables  $\psi(t, s)$  with the initial condition  $\psi(0, s) = s$ .

## Theorem 5 ...

- ▶ **Proof of Part 2** Consider

$$\phi(v+h; s) = \phi(v; \phi(h; s))$$

- ▶ By Taylor's theorem, we get

$$\phi(v+h; s) = \phi(v; s) + hu(\phi(v; s)) + o(h)$$

- ▶ Hence

$$\frac{\phi(v+h; s) - \phi(v; s)}{h} = u(\phi(v; s)) + \frac{o(h)}{h}$$

So we have proved the first part of theorem five. Similarly one can prove the second part of theorem five. The proof of a part two. You start with the probability generating function  $\psi$  of  $v$  plus  $h$ ,  $s$  is same as  $\psi$  of  $v$ ,  $\psi$  of  $h$ ,  $s$ . By Taylor's theorem the right hand side becomes  $\psi$  of  $v$ ,  $s$  plus  $h$  of  $u$   $\psi$  of  $v$ ,  $s$  plus order of  $h$ . Then  $\psi$  of  $v$ ,  $s$  in the left hand side divide throughout by  $h$  we will get this equation. Now limit  $h$  tends to  $0$  plus and then substitute  $v$  is equal to  $t$  in this equation limit  $h$  tends to  $0$  plus and substitute the  $v$  is equal to  $h$ ,  $v$  is equal to  $t$  we get partial derivative of  $\psi$  with respect to  $t$  is equal to  $u$  of  $\psi$  of  $t$ ,  $s$ . This is ordinary differential equation with the initial condition  $\psi$  of  $0$ ,  $s$  equal to  $s$ . So in the theorem 5 we conclude the probability generating function satisfies the partial differential equation and the initial and ordinary differential equation with the initial conditions  $\psi$  of  $0$ ,  $s$  equal to  $s$ .

**Theorem 5 ...**

- ▶ Taking  $h \rightarrow 0^+$ , then substituting  $v = t$ , we get

$$\frac{\partial \phi(t; s)}{\partial t} = u(\phi(t; s))$$

- ▶ This is an ordinary differential equation with initial condition

$$\phi(0; s) = \sum_j P_{ij}(0) s^j = s$$

Now we will find out the mean of  $Z$  of  $t$ . You start with the partial differential equation satisfied by probability generating function. By differentiating with respect to  $s$  and the interchanging the order of differentiation on the left-hand side we get the left-hand side is the second order partial derivative of  $\psi$  with respect to  $t$  and with respect to  $s$ . The right hand side  $u$  of  $s$  second order partial derivative of  $\psi$  with respect to  $s$   $u$  dash of  $s$  partial derivative of  $\psi$  with respect to  $s$ . If  $s$  equal to  $1$  you know that  $u$  of  $1$  will be  $0$ . Suppose the  $m$  of  $t$  will be the mean of  $Z$  of  $t$  that is nothing but the partial derivative of  $\psi$  with respect to  $s$  then substitute  $s$  is equal to  $1$ . Therefore this equation becomes partial derivative of  $m$  of  $t$  with respect to  $t$  is equal to  $u$  dash of  $1$   $m$  of  $t$  since  $m$  is the single variable so this is the ordinary differential equation. So  $dm$  by  $dt$  is equal to  $u$  dash of  $1$  times  $m$  of  $t$  where  $m$  of  $t$  is a mean of  $Z$  of  $t$ . But since  $Z$  of  $0$  is equal to  $1$   $m$  of  $0$  also  $1$ . Therefore you can solve this ordinary differential equation. The initial condition  $m$  of  $0$  is equal to  $1$  hence the solution will be  $m$  of  $t$  is equal to  $e$  power  $t$  times  $u$  dash of  $1$ .

## Mean of $Z(t)$

- ▶ Consider

$$\frac{\partial \phi(t; s)}{\partial t} = \frac{\partial \phi(t; s)}{\partial s} u(s)$$

- ▶ By differentiating with respect to  $s$  and interchanging the order of differentiation on the left side, we get

$$\frac{\partial^2 \phi(t; s)}{\partial t \partial s} = u(s) \frac{\partial^2 \phi(t; s)}{\partial s^2} + u'(s) \frac{\partial \phi(t; s)}{\partial s}$$

Now we can discuss the mean of  $Z$  of  $t$  based on the value of  $u$  dash of 1. Before that we discuss the probability of extinction. That is defined by  $q$  that is nothing but limit  $t$  tends to infinity probability of 1,0 of  $t$ . This is called a probability of extinction that is denoted by the letter quarter.

## Mean of $Z(t)$ ...

- ▶ If  $s = 1$ ,  $u(1) = \sum_k a_k = 0$ , and then

$$\frac{\partial m(t)}{\partial t} = u'(1)m(t)$$

where

$$m(t) = E[Z(t)] = \left. \frac{\partial \phi(t; s)}{\partial s} \right|_{s=1}$$

- ▶ But, since  $Z(0) = 1$ , then  $m(0) = 1$  and the solution is

$$m(t) = e^{u'(1)t}$$

Now we will try to find out the probability of extinction  $q$ . Assume that a naught is strictly greater than 0 otherwise extinction is impossible. It is an enough to consider the case where the process starts with a single individual at time 0. It means  $Z$  of 0 is equal to 1. With  $s$  equal to 0 you will get a  $P_i$  of 0 of  $t$  that is nothing but a  $P_{10}$  of  $t$  power  $i$  in the probability generating function of  $P_{ij}$  of  $t$ .

## Definition

- ▶ The extinction probability,  $q$ , is defined by

$$q = \lim_{t \rightarrow \infty} P_{10}(t)$$

Now we will prove that  $P_{ij0}$  of  $t$  is a non decreasing in  $t$ . You start with  $P_{i0}$  of  $t$  plus  $v$  that is nothing but  $\psi$  of  $t$  plus  $v,0$  of power  $i$  that is same as  $\psi$  of  $t$ ,  $\psi$  of  $v,0$  power  $i$  that will be greater than or equal to  $\psi$  of  $0,t$  power  $i$  but that is same as  $P_{i0}$  of  $t$ . Hence we proved  $P_{i0}$  of  $t$  is a non decreasing in  $t$ .

## Probability of Extinction

- ▶ Now, we assume that  $a_0 > 0$ , otherwise extinction is impossible.
- ▶ It is enough to consider the case where the process starts with a single individual at time zero.
- ▶ In fact, with  $s = 0$

$$P_{i0}(t) = [P_{10}(t)]^i$$

- ▶ Now,  $P_{i0}(t)$  is non-decreasing in  $t$ ,

$$\begin{aligned} P_{i0}(t + v) &= [\phi(t + v; 0)]^i \\ &= [\phi(t; \phi(v; 0))]^i \\ &\geq [\phi(t; 0)]^i \\ &= P_{i0}(t) \end{aligned}$$

Let  $t$  be the fixed positive number consider a discrete time branching process  $Z$  of 0,  $Z$  of  $t$  naught,  $Z$  of 2 times  $Z$  naught and so on,  $Z$  of  $n$  times  $t$  naught where  $Z$  of  $t$  is population size at time  $t$ . Assume that the population size at time 0 is 1,  $Z$  of 0 is equal to 1. Since  $Z$  of  $t$  is assumed to be Markov process the discrete process  $Y_n$   $Y$  suffix  $n$  that is nothing but  $Z$  of  $n$  of  $t$  naught will be a discrete time Markov chain which is also a discrete time branching process because  $Z$  of  $t$  is a continuous time branching process therefore  $Y$  of  $n$  will form a discrete-time branching process which is also a discrete time Markov chain. By the hypothesis of homogeneity of probability function of  $Z$  of  $t$  and the probability generating function of  $P_{ij}$  of  $t$  that is nothing but probability generating function of  $P_{1j}$  of  $t$  power  $P_1$  of  $1$   $j$  of  $t$  power  $i$ .

This we have proved it in the earlier. We have proved it in earlier therefore using these two we are finding summation over  $k$  the conditional probability of  $Y_{n+1}$  is equal to  $k$  given  $Y_n$  is equal to  $i$  multiplied by  $s$  power  $k$  that is nothing but expectation of  $s$  power  $Y_{n+1}$  given  $Y_n$  is equal to  $i$ . That is same as because  $Y_n$  is nothing but  $Z$  of  $n$  times  $t$  naught therefore  $Y_{n+1}$  is nothing but  $Z$  of  $Y_{n+1}$  times  $t$  naught. So it implies  $Y_n$  by  $Z_n$   $n$  times  $t$  naught and  $Y_{n+1}$  by  $Z$  of  $n+1$  times  $t$  naught. This is true for all  $n$  therefore that the same as expectation of  $s$  power  $Z$  of  $t$  naught given  $Z$  of 0 is equal to  $i$  but that is nothing but  $\psi$  of  $t$  naught,  $s$  power  $i$  but that can be written as expectation of  $s$  power  $Z$  of  $t$  naught given  $Z$  naught is equal to 1 whole power  $i$  that is same as expectation of  $s$  power  $Y_1$  given  $Y$  naught is equal to 1 the whole power  $i$ . This shows that  $Y_n$  is a branching process.  $Y_n$  is a discrete-time branching process. So using this we have proved the  $Y_n$  is a discrete time branching process. The probability generating function for the number of offspring of a single individual in this process is  $\psi$  of  $t$  naught,  $s$ . By theorem 3 we know that the probability of extension for  $Y_n$  that is a discrete time branching process is the smallest non-negative root of the equation  $\psi$  of  $t$  naught,  $s$  equal to  $s$ .

## Derivation of Probability of Extinction ...

- ▶ The probability generating function of the number of offspring of a single individual in this process is  $\phi(t_0; s)$ .
- ▶ By Theorem 3, we know that the probability of extinction for the  $Y_n$  process is the smallest non-negative root of the equation

$$\phi(t_0; s) = s$$

- ▶ But

$$\begin{aligned} P(Y_n = 0 \text{ for some } n) &= \lim_{n \rightarrow \infty} P(Y_n = 0) \\ &= \lim_{n \rightarrow \infty} P(Z(nt_0) = 0) \\ &= \lim_{t \rightarrow \infty} P(Z(t) = 0) \\ &= q \end{aligned}$$

So by using the theorem 3 we conclude the probability of extinction for the  $Y_n$  process is the smallest non-negative root of the equation  $\phi(t_0; s) = s$ . But we know that probability of  $Y_n$  is equal to 0 for some  $n$  that is same as limit  $n$  tends to infinity of probability of  $Y_n$  is equal to 0 that is same as a limit  $n$  tends to infinity of a probability of  $n$  times  $Z$  naught is equal to 0 but that is same as limit  $t$  tends to infinity of probability  $Z_t$  is equal to 0. By definition this is nothing but  $q$  that is a probability of extinction.

## Derivation of Probability of Extinction ...

- ▶ The extinction probability  $q$  of the continuous time branching process  $Z(t)$  is the smallest non-negative root of the equation

$$\phi(t_0; s) = s$$

where  $t_0$  is any positive number.

- ▶ Hence, we expect that we should also be able to calculate  $q$  from an equation that does not depend on time.

Hence the probability of extinction  $q$  of a continuous time branching process  $Z$  of  $t$  is the smallest non-negative root of the equation  $\psi(t; s) = s$ . Here we have concluded by theorem 3 the probability of extinction for the discrete-time branching process  $Y_n$  is the smallest non-negative root of the equation  $\psi(t; s) = s$  because of this we conclude the probability of extinction of the continuous-time branching process  $Z$  of  $t$  is a smallest non-negative root of the equation  $\psi(t; s) = s$  where  $t$  is any positive number. Hence we expect that we should be able to calculate  $q$  from an equation that does not depend on time. From this equation we can calculate  $q$  from the equation that does not depend on time.
