

**Convex Optimization**  
**Prof. Joydeep Dutta**  
**Department of Mathematics and Statistics**  
**Indian Institute of Technology, Kanpur**

**Lecture No. # 39**

So, it is almost time to say good bye to all of you, because this is the so called last truly **the sorry** the last lecture of this course. This course is supposed to be 40 lectures, 39 lectures are for the real course and the 40th lecture is supposedly a summarization of what is done, but I know that if I summarize things it will bore you. So, in the last lecture, I will give you what is called an entertainment lecture which would be of completely different flavor, but doing optimization at bit level which is higher then what we have been doing.

But let us mentioning that at this point what we are doing is really not a under grade level thing. It is a grade level thing largely for more for those students who are involved in some research using optimization techniques especially convex optimization techniques. So, we are going to start by talking about minimization of d c functions and minimization of this form **right**.

(Refer Slide Time: 01:24)

$$-\lambda_0 \|\hat{x} - \hat{z}\|^2 + \langle \eta_i, \hat{z} - \hat{x} \rangle < 0$$

Minimization of d.c. functions

$\min f(x) - g(x), \text{ subject to } x \in C \text{ (P2)}$

$C = \mathbb{R}^n$  : Then if  $\bar{x}$  is a (local) or global min of (P2) then  
 $\partial g(\bar{x}) \subseteq \partial f(\bar{x})$

This condition is really necessary but not sufficient for  $\bar{x}$  to be the global minimum of (P2).

→  $\epsilon$ -subdifferential. ( $\epsilon > 0$ )

$$\partial_\epsilon f(\bar{x}) = \{ \beta \in \mathbb{R}^n : f(y) - f(\bar{x}) \geq \langle \beta, y - \bar{x} \rangle - \epsilon \quad \forall y \in \mathbb{R}^n \}$$

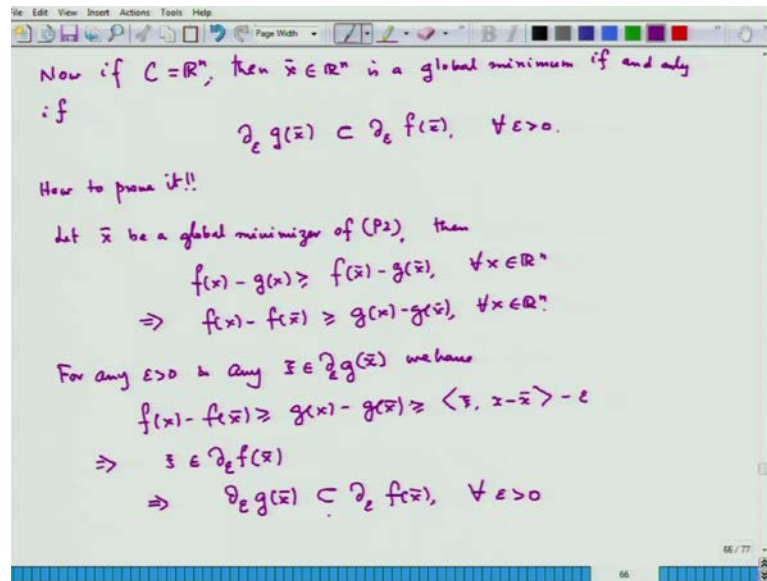

$\partial_\epsilon f(\bar{x}) \neq \emptyset$  for any  $\epsilon > 0$ .

So, first we had considered the case  $C$  is equal to  $\mathbb{R}^n$ , then if  $f$  is a local or global min of this problem which we called  $p_2$ , then we know that **the** **sorry** if  $\bar{x}$  is a local,  $\text{del } g$  of  $\bar{x}$ . However, this condition is really necessary, is not sufficient. This condition is really necessary and not sufficient, but for convex optimization problems we have necessary and sufficient condition for global minimization. So, it is quite natural to ask that this even though these problems are non-convex, because if you have a twice contiguous differentiable function, you can write it as a  $d$   $c$  function.

So, even if this function is non-convex, can I tell something more about it that is it possible to give at least mathematically, theoretically if an only if condition for existence of a global minimum. So, a necessary and sufficient condition for existence of global minimum, but not sufficient for  $\bar{x}$  to be the global minimum **to be the global minimum** of  $p_2$ . So, what you really need to do is **the** ask a question, is it possible to give such a condition - a necessary and sufficient condition for  $\bar{x}$  to be a global minimum. In that we and the answer surprisingly is easiest and our tool is a epsilon sub-differential.

And I would again like to recall you that if  $f$  is a convex function from  $\mathbb{R}^n$  to  $\mathbb{R}$ , and the epsilon sub-differential at  $\bar{x}$  given an epsilon greater than 0 is the set of all vector  $\psi$  in  $\mathbb{R}^n$  which satisfies a following inequality.  $\psi \text{ inner product } y - \bar{x} - \epsilon$  for all  $y$  in  $\mathbb{R}^n$ . It will be important to note that  $\text{del } e f(\bar{x})$  is always non-empty for any epsilon greater than 0. Though it has some drawbacks like even if the function is differentiable we cannot say much about the derivative here, much about that **that** **(( ))** only a single **(( ))** set; no, it is not necessarily. So however, it helps us in studying this kind of problems.

(Refer Slide Time: 05:08)

Now, if  $C$  is equal to  $\mathbb{R}^n$  then  $\bar{x}$  element of  $\mathbb{R}^n$  is a global minimum of  $p_2$ . Now, we are doing only for the unconstrained case; we are not doing anything for the constrained case. See we will see most of our problem is for the unconstrained case, so you might be quite surprised that we have not given any condition for the constrained case. Here giving a condition for the constrained case is supposedly slightly difficult, and but it is not so difficult as we think so; we will try to see what we can do. Let us have a look at things.

First let us wait for this  $\mathbb{R}^n$  case and then try to apply. So, then if  $\bar{x}$  is a global minimum if and only if.

(No audio from 06:14 to 06:31)

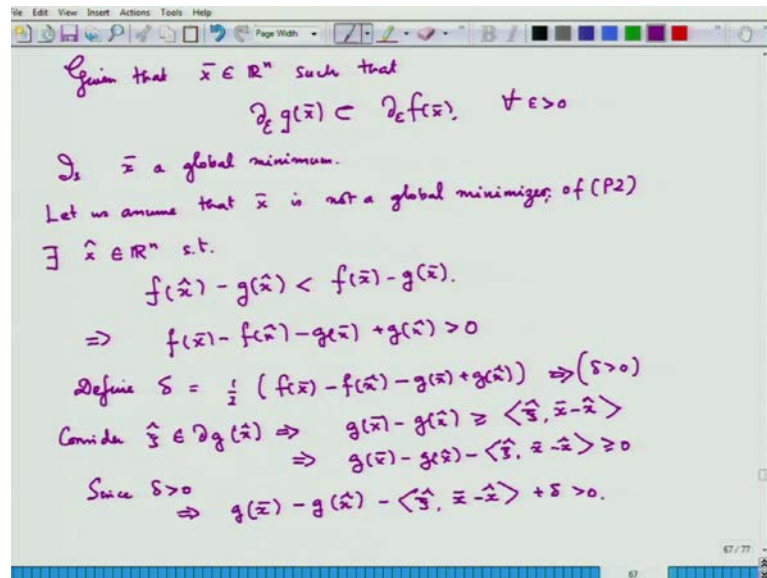

This, now this problem as  $(( ))$ , this has to be true for all  $\epsilon$  greater than 0 **right**, for all  $\epsilon$  greater than **if** 0 if this is true then this  $\bar{x}$  is a global minimum of the  $d_c$  problem unconstrained  $d_c$  problem. So, let us write to prove this **right**. So, the question is how to prove it. So, let us start with the fact that - let  $\bar{x}$  be a global minimizer of  $p_2$ .

(No audio from 07:11 to 07:22)

Then  $f(x) - g(x)$  is greater than equal to  $f(\bar{x}) - g(\bar{x})$  for all  $x$  in  $\mathbb{R}^n$ , which implies that  $f(x) - f(\bar{x})$  is greater than equal to  $g(x) - g(\bar{x})$  for all  $x$  in  $\mathbb{R}^n$ . For any  $\epsilon$  greater than 0 and any  $\psi$  element of, we have  $f(x) - f(\bar{x})$  bigger than  $g(x) - g(\bar{x})$  then applying the optimality condition. This is

exactly same as writing now; I will just apply the definition of the epsilon sub differential which is this, which will give me a following. This would imply that psi is element of del epsilon f(x bar). So, it will imply that del epsilon g(x bar) is subset of del epsilon f(x bar) for all epsilon del epsilon sub differential of g at x bar is containing the epsilon sub differential of f at x bar for all epsilon greater than 0.

(Refer Slide Time: 09:17)

Now, the question is, given that x bar is element of R n such that del epsilon of g of x bar subset of del epsilon of f of x bar for all epsilon greater than 0. Question is, is x bar a global minimum? So, you have the (( )) becomes slightly interesting and let us see how do we do it. So, let us assume that x bar is not a global minimizer, so they there exists x at element of R n such that f of x hat minus g of x hat is strictly less than f of x bar minus g of x bar. So, now we will have this. Now, what we have done is said to be assume that x bar is not a global minimum, so we will get this. Now, how do I prove it? This is again a proof by contradiction which means that if x bar is not a global minimizer of the problem p2, then I have to show some contradiction arising. So, let me write this as f(x bar) minus f(x star) minus g(x bar) plus g(x star) strictly bigger than 0, and define...

(No audio from 11:15 to 11:22)

So, what will show? We define this positive number delta and will show that delta is strictly less than delta which is impossible. I said delta to be this, so naturally delta is greater than 0. Now, consider psi had element of del g(x hat), note it is not the epsilon

sub differential just a sub differential. So, this would imply that  $g(\bar{x}) - g(\hat{x})$  is greater than equal to  $\psi \hat{x} - \bar{x} - \delta$ . So that implies that  $g(\bar{x}) - g(\hat{x})$  minus of this part. This is clear. Now, since  $\delta$  is greater than 0, it would imply that if I add  $\delta$  to this quantity it will become strictly greater than 0, because to a non-negative quantity of added up strictly positive quantity, so that would be strictly greater than 0.

(Refer Slide Time: 13:06)

Define  $\epsilon = g(\bar{x}) - g(\hat{x}) - \langle \hat{\xi}, \bar{x} - \hat{x} \rangle + \delta \Rightarrow (\epsilon > 0)$

For  $x \in \mathbb{R}^n$ , note that

$$\left. \begin{aligned} \langle \hat{\xi}, x - \bar{x} \rangle - \epsilon &= \langle \hat{\xi}, x - \hat{x} + \hat{x} - \bar{x} \rangle - \epsilon \\ &= \langle \hat{\xi}, x - \hat{x} \rangle - \delta + g(\hat{x}) - g(\bar{x}) \end{aligned} \right\}$$

Now as  $\hat{\xi} \in \partial g(\hat{x}) \Rightarrow \hat{\xi} \in \partial_{\delta} g(\bar{x})$ .

$$g(x) \geq g(\hat{x}) + \langle \hat{\xi}, x - \hat{x} \rangle - \delta$$

$$\Rightarrow \langle \hat{\xi}, x - \bar{x} \rangle - \epsilon \leq g(x) - g(\bar{x})$$

$$\Rightarrow \hat{\xi} \in \partial_{\epsilon} g(\bar{x}) \Rightarrow \hat{\xi} \in \partial_{\epsilon} f(\bar{x})$$

In particular for  $x = \hat{x} \Rightarrow f(\hat{x}) - f(\bar{x}) \geq \langle \hat{\xi}, \hat{x} - \bar{x} \rangle - \epsilon$

Now, this is again a positive quantity and will define an epsilon. So, for that epsilon the given hypothesis will hold. So, I will define epsilon equal to...

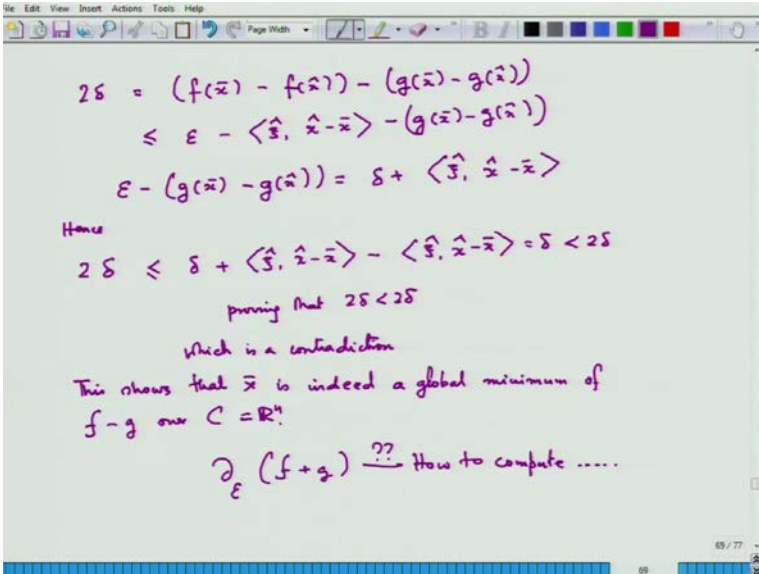

(No audio from 13:17 to 13:27)

$\psi \hat{x} - \bar{x} - \delta$ , so naturally epsilon, this should again imply that epsilon is greater than 0. This is very simple and straight forward and clear. Now, for any  $x$  in  $\mathbb{R}^n$ , note that  $\psi \hat{x} - \bar{x} - \delta$  can be written as  $\psi \hat{x} - \bar{x} - \delta + g(\hat{x}) - g(\bar{x})$ , which when I write down the definition of epsilon would lead to the fact that  $\psi \hat{x} - \bar{x} - \delta + g(\hat{x}) - g(\bar{x})$ . So, here  $\psi \hat{x} - \bar{x} - \delta$  will cancel with when I put minus will cancel with  $\psi \hat{x} - \bar{x} - \delta$ . So, what will get is this one.

Now, as  $\psi \hat{x}$  is element of  $\partial g(\hat{x})$ , it implies very simply that  $\psi \hat{x}$  is also element of  $\partial_{\delta} g(\bar{x})$ . Now, once you know this **sorry** you will immediately write

$g$  of  $x$  is bigger than  $g$  of  $x$  hat plus epsilon hat  $x$  minus  $x$  hat minus delta. So, this would immediately show from this above expression from this expression here from this expression that  $\psi$  hat  $x$  minus  $x$  bar minus epsilon is less than  $g(x)$  minus  $g(x$  bar). This is true for any  $x$ , because  $x$  was arbitrary for **x element of  $\mathbb{R}^n$**  any  $x$  element of  $\mathbb{R}^n$  which implies that  $\psi$  hat is element of  $\delta$  epsilon  $g(x$  bar). This also implies by a hypothesis that  $\psi$  hat is element of  $\delta$  epsilon  $f$  of  $x$  bar. **So...** So, in particular for  $x$  equal to  $x$  hat it implies that  $f$  of  $x$  hat minus  $f$  of  $x$  bar is bigger than  $\psi$  hat times  $x$  hat minus  $x$  bar minus epsilon.

(Refer Slide Time: 17:02)

$$\begin{aligned}
 2\delta &= (f(\bar{x}) - f(\hat{x})) - (g(\bar{x}) - g(\hat{x})) \\
 &\leq \epsilon - \langle \hat{\xi}, \hat{x} - \bar{x} \rangle - (g(\bar{x}) - g(\hat{x})) \\
 \epsilon - (g(\bar{x}) - g(\hat{x})) &= \delta + \langle \hat{\xi}, \hat{x} - \bar{x} \rangle \\
 \text{Hence} \\
 2\delta &\leq \delta + \langle \hat{\xi}, \hat{x} - \bar{x} \rangle - \langle \hat{\xi}, \hat{x} - \bar{x} \rangle = \delta < 2\delta \\
 &\text{proving that } 2\delta < 2\delta \\
 &\text{which is a contradiction} \\
 &\text{This shows that } \bar{x} \text{ is indeed a global minimum of} \\
 &f - g \text{ over } C = \mathbb{R}^n \\
 &\partial_{\epsilon} (f + g) \quad ?? \text{ How to compute } \dots
 \end{aligned}$$

Now, if you go back to the definition of delta, then from there you can write 2 delta is equal to  $f$  of  $x$  bar minus  $f$  of  $x$  hat minus  $g$  of  $x$  bar minus  $g$  of  $x$  hat. Now, this from here, you know this is nothing but epsilon minus  $\psi$  hat into  $x$  hat minus  $x$  bar, just what you got before you are writing them now is minus of  $g(x$  bar) minus of  $g(x$  hat) in bracket, so minus  $g(x$  bar) plus  $g(x$  hat).

Now, once you know that epsilon minus  $g(x$  bar) the way epsilon is defined, if you will go back to the definition of epsilon then what you get, epsilon minus this is delta minus this. So, is delta plus epsilon hat into **not** it will be slightly will just **(( ))** of help just putting the correct sign, putting an better sign,  $x$  hat minus  $x$  bar rather than  $x$  bar minus  $x$  hat. Hence from this here 2 delta is less than equal to delta epsilon minus this is delta plus epsilon hat  $x$  hat minus  $x$  bar minus epsilon hat  $x$  hat minus  $x$  bar is equal to delta

which is strictly less than  $2\delta$ ; proving that  $2\delta$  is strictly less than  $2\delta$  which is a contradiction. This shows that  $\bar{x}$  is indeed a global minimum of  $f$  minus  $g$  over  $C$  equal to  $\mathbb{R}^n$ . It is important to realize at the very instant that in this last lecture. You may now ask me the question why I am always about putting  $C$  is equal to  $\mathbb{R}^n$  for this case. If I am not putting  $C$  2, we just a closed convex set - subset of  $\mathbb{R}^n$  - a proper subset of  $\mathbb{R}^n$ .

The answer is that yes, it can be done, it can be done and the problem is that even if it can be done, one has to realize that **they** we would get into certain technical it is specially with the sum of or if you take the sum of two function, basically now if I want to do for the case when  $C$  is a close convex set, I need to answer you this question, what is this, how to compute this. So, this would be getting into too much of technicality keeping in view the level of this course, such a technicality is really not required at this stage. For I can show you something quite interesting that you can use this idea what we have just proved to devise a very simple looking necessary and sufficient optimality condition for maximization of the convex function over a convex set.

(Refer Slide Time: 21:07)

$$N_C^\epsilon(\bar{x}) = \{v \in \mathbb{R}^n : \langle v, x - \bar{x} \rangle \leq \epsilon, \forall x \in C\}$$

$$\text{If } \epsilon = 0 \text{ then } N_C^\epsilon(\bar{x}) = N_C(\bar{x}).$$

$$\text{If } \epsilon > 0 \text{ } N_C^\epsilon(\bar{x}) \text{ is no longer a cone } \dots \text{ it is just a set.}$$

$$\text{Now given } \epsilon > 0, \exists \bar{x} \in C, \text{ s.t.}$$

$$0 \in \partial_\epsilon f(\bar{x}) + N_C^\epsilon(\bar{x}) \quad [f \text{ is a convex fn}]$$

$$\Rightarrow 0 = \xi + v$$

$$\quad \quad \downarrow \quad \downarrow$$

$$\quad \quad \partial_\epsilon f(\bar{x}), N_C^\epsilon(\bar{x})$$

$$f(x) - f(\bar{x}) \geq \langle \xi, x - \bar{x} \rangle - \epsilon$$

$$\text{But } \xi = -v \Rightarrow f(x) - f(\bar{x}) \geq \langle -v, x - \bar{x} \rangle - \epsilon$$

$$\Rightarrow f(x) - f(\bar{x}) \geq -\epsilon - \epsilon$$

$$\Rightarrow f(x) - f(\bar{x}) \geq -2\epsilon \Rightarrow \bar{x} \text{ is an } 2\epsilon\text{-min of } f \text{ over } C.$$

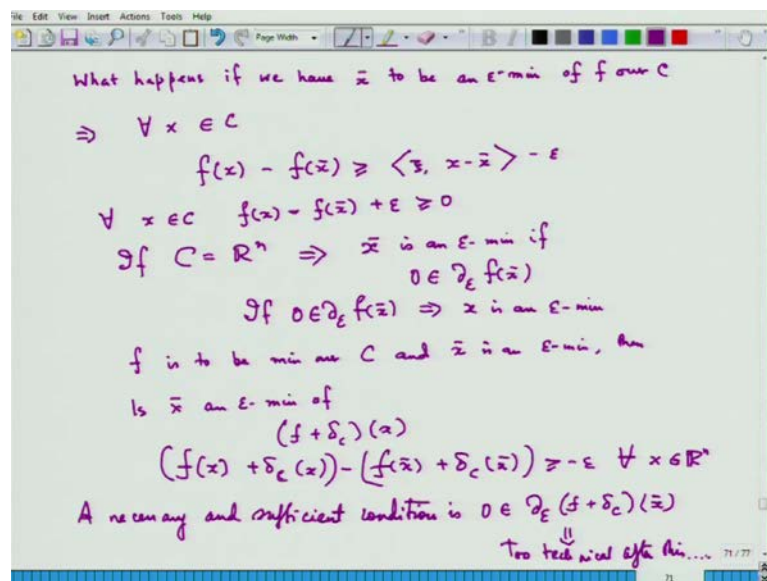

In order to do so we will introduce this idea of the epsilon normal set to  $C$  at  $\bar{x}$ , it is a set of all  $v$  in  $\mathbb{R}^n$  such that  $v$  times  $x$  minus  $\bar{x}$  is less than epsilon for all  $x$  in  $C$ . So, if epsilon is equal to 0, then this is nothing but the standard normal cone that we know in  $C$  at  $\bar{x}$ . But if epsilon is greater than 0, this is **no longer** no longer a cone, it is just a set **it is just a set**. Now, there is some interesting about it, is that suppose minus of  $\psi$ , now there

is suppose 0 **suppose there is** suppose I have the following condition; suppose now given  $\psi$  greater than 0, there exist  $\bar{x}$  element of  $C$  such that you see  $f$  is always a convex function such that 0 belongs to  $\partial_\epsilon f(\bar{x}) + N$ ;  $f$  is a convex function,  $C$  is a convex set, and  $C$  is a convex set it is standardized. Then let us see from here what can we get. It would imply that 0 is equal to  $\psi$  plus  $v$  where this belongs to...

(No audio from 23:17 to 23:25)

So, this imply **f of x bar**  $f$  of  $x$  minus  $x$  bar is greater than equal to  $\psi$  times  $x$  minus  $x$  bar minus  $\epsilon$ . But  $\psi$  is equal to minus of  $v$ , so this would imply that  $f$  of  $x$  minus  $f$  of  $x$  bar is greater than equal to minus of  $v$  inner product  $x$  minus  $x$  bar minus  $\epsilon$ . But this **this** shows that this thing by the fact that  $v$  belongs to this; this is greater than equal to  $\epsilon$ . So, this would immediately imply that  $f(x)$  minus  $f(x$  bar) is greater than equal to minus  $\epsilon$  **right**. So, minus  $\epsilon$  minus  $\epsilon$ , so this would imply that  $f(x)$  minus  $f(x$  bar) is greater than equal to minus 2  $\epsilon$ ; prove it implying that  $x$  bar **is a** is an  $2\epsilon$  min of  $f$  over  $C$ . So, if you have both the same  $\epsilon$ s here what you get is  $2\epsilon$  min. It is not the same  $\epsilon$  min **right**. So, you see things what do you know about is very handle **(( ))** handle  $\epsilon$  sub differentials and approximate minimum  $\epsilon$  min things are slightly different.

(Refer Slide Time: 25:27)

Now, what happens if we have  $\bar{x}$  to be an  $\epsilon$  min of  $f$  over  $C$ , so this would imply for all  $x$  element of  $C$ ,  $f$  of  $x$  minus  $f$  of  $x$  bar is greater than equal to  $\psi$  times  $x$

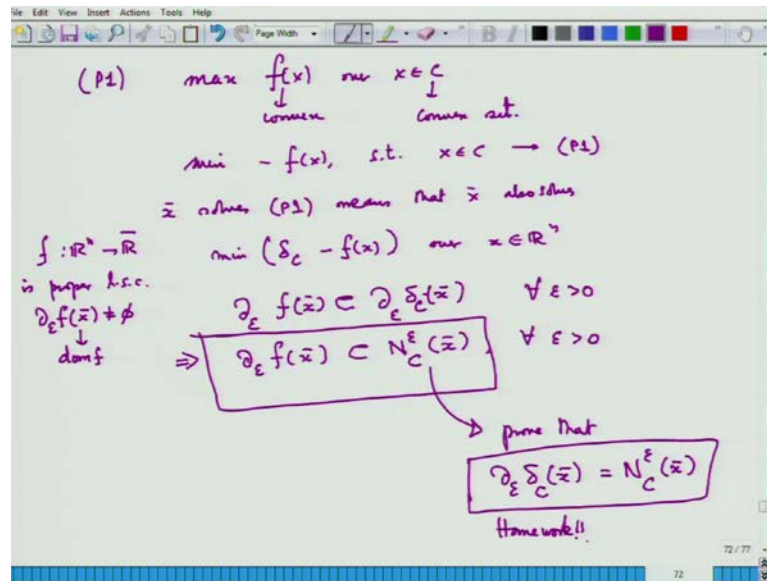

minus  $\bar{x}$  minus  $\epsilon$ . So, for all  $x$  it implies that  $f(x)$  minus  $f(\bar{x})$  plus  $\epsilon$  is bigger than equal to 0 for all  $x$  in  $C$  sorry. So, this is known to be greater than 0, so if 0 is element of  $\delta \epsilon$ . So now, what I am having is the following. I am having that  $\psi$  times  $x$  minus  $\bar{x}$ , this one; if I put a 0 here, if 0 belongs to this you see. So, if we now from there how do I figure out some necessary condition. Suppose this is true for all  $x$ , then if I put  $\psi$  equal to 0 the condition is satisfied. But then if I put  $\psi$  equal to 0 this condition is not true for all elements of  $C$ ,  $\psi$  so when 0 element of  $\psi$  they would 0. This is only true for this fact is only true for all  $x$  element of  $C$ . So, for all  $x$  element of  $\mathbb{R}^n$ , this fact might not become true.

So, if  $x$  is equal to  $\bar{x}$  if  $C$  is equal to  $\mathbb{R}^n$ , now now if I choose if  $C$  is equal to  $\mathbb{R}^n$ , then it would imply that  $\bar{x}$  is an  $\epsilon$  min, if 0 is element of  $\delta \epsilon$ . Again if 0 is element of  $\delta \epsilon$   $f(\bar{x})$  it implies that  $\bar{x}$  is an  $\epsilon$  min. Now, the interesting part is that this fact this fact is not so easy when you make the problem constraint. This analyzing  $\epsilon$  minimum that is exactly what is I shown in. So, in unconstraint case, it is much more simple. So, you can say ok, then what I can do is, if  $f$  is to be minimized over  $C$  and  $\epsilon$  and  $\bar{x}$  is an  $\epsilon$  min, then is  $\bar{x}$  an  $\epsilon$  min of  $f$  plus  $\delta C \bar{x}$ ; answer looks like yes, because you see if I take  $f$  of  $x$  plus  $\delta C x$  plus  $f$  of  $x$  minus plus  $f$  of  $\bar{x}$  sorry minus  $f$  of  $\bar{x}$  plus  $\delta C \bar{x}$ , then observe that when this is 0.

When  $C$  is in  $x$ , this is always greater than minus infinity, minus  $\epsilon$ , and when  $C$  is when sorry when  $x$  is in  $C$  this is 0, so  $f(x)$  minus  $f(\bar{x})$  is any way bigger than minus  $\epsilon$  that is given to you. And if  $C$  is not in  $x$ , then this becomes plus infinity, so anyway that whole thing is bigger than minus infinity  $\epsilon$ . So, it implies that this is greater than equal to minus  $\epsilon$  for all  $x$  element of  $\mathbb{R}^n$ . So, a necessary and sufficient condition is 0 belonging to  $\delta \epsilon$  of  $f$  plus  $\delta C \bar{x}$ . Now, if I want to expand it again this question of some rule will come and here we have all lower semi continuous function and so there will lot of too technical after this.

(Refer Slide Time: 31:33)

So, we will go back to our problem of maximizing or the problem p1 of maximizing  $f(x)$  over  $x$  element of  $C$  which give again this is a convex function and this is a convex set. Let us handle this situation bit interestingly, I can pose this problem as minimize minus  $f(x)$  such that  $x$  is belonging to  $C$ . Now, if I put the  $\phi(x)$  as the 0 function, then  $\bar{x}$  solves the same as p1, p1 it means that  $\bar{x}$  also solves min of  $\delta_C$  minus  $f(x)$  over  $x$  element of  $\mathbb{R}^n$ . And for this optimality condition is known to us; optimality condition is  $\partial_\epsilon f(\bar{x})$ .

Now, you can say why **why** are you talking about  $\delta_C$  now? Now, here the optimality condition that we have given, if you look slightly carefully can be extended to the case where this can be extended to the case where you have an extended valued lower semi continuous functions. So, if even if  $f$  from  $\mathbb{R}^n$  to  $\bar{\mathbb{R}}$  is actually lower semi continuous is  $\mathbb{R}^n$  to  $\bar{\mathbb{R}}$  is proper l.s.c which is the case of this function. You can similarly, for every  $\bar{x}$  in the domain of  $f$ , you can define  $\partial_\epsilon f(\bar{x})$  and for any element in the domain of  $f$  you will have this. Actually what you need to know is that you can now basically, if you have  $\bar{x}$  in the domain of  $f$  does not matter. So, this **this** will be not equal to  $\phi$ . So, it does not matter even if you have lower semi continuous function. So, even if your one function continuous, suppose your  $f$  minus  $g$  is a lower semi continuous and  $g$  is a continuous and  $f$  is lower semi continuous, then also you will have the similar relation  $\partial_\epsilon (f(x) - g(x)) \subset \partial_\epsilon f(x) - \partial_\epsilon g(x)$  in bracket of  $\partial_\epsilon$  is subset of  $\dots$ . So, you will have this relation, this relation will hold  $\partial_\epsilon (f(x) - g(x)) \subset \partial_\epsilon f(x) - \partial_\epsilon g(x)$  in this particular case,

this the lower semi continuous function would be on the other side. So, you have just applied what you have learned.

So, what you have known, so whatever we had this **this** result, what we have learned here that if this happen then  $\bar{x}$  is a global minima, when  $f$  and  $g$  are both finite valued function, but  $f$  is a proper lower semi continuous convex function. Then this is always non-empty, if  $\bar{x}$  is an element of domain, so for any element  $\bar{x}$  in the domain in this case  $C \bar{x}$  is in  $C$  which is in the domain. This result will also hold true, if  $g$  is a finite valued function and  $f$  is lower semi continuous and convex, this result will also hold in a very, very straight forward fashion. The proof can be very simply modified, so I am not mention this.

So, now I will have this **this** thing, so for all epsilon greater than 0. So, this would imply and it will be your home work to figure out that this is nothing but this set. So, here is a neat looking necessary and sufficient optimality condition for maximization or finding a global maxima of a convex function, but you really that this is not so easy to prove, because... But is not easy to **sorry** it is easy to prove, but it is not so easy to compute and really verify, because the problem, this sort of conditions run into difficulties, because we have for all epsilon greater than equal to 0. Can this condition we improved, so that they are much more hand able in actual computation. So, this is a hard non-convex problem and this to improve these conditions is a challenge which is still not even answer. **Sorry** you can see.

So, this you prove as homework. This is very, very simple, just the definition. With this I would like to end today's talk and this course, basically ends here. Thank you for listening to this a long 39 session journey. The last talk, the 48th one, instead of summarizing I will give you a different flavor what I would say I will give you an entertainment lecture, and where all show you some very festinating aspect of quadratic optimization, and I show you how semi definite programming would play a role there. Thank you very much.
