**Lecture – 21**  
**Multivariate Analysis - VI**

In the last lectures, I have introduced multivariate versions of the chi square distribution, which we call Wishart distribution, we also considered multivariate version of the student's t distribution, which we called Hotelling's T square distribution, we also see some other distribution such as non-central chi square, non-central t and non-central f and I showed a couple of applications where they arise.

**(Refer Slide Time: 01:11)**

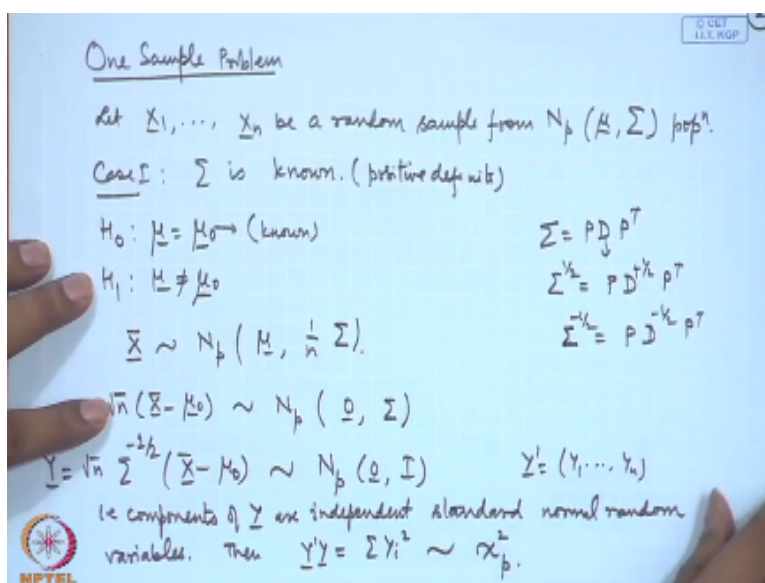

Basically, these distributions will be used when we consider testing in the multivariate normal population. If you remember the earlier lectures on the testing of hypothesis, we have introduced the testing for the parameters of a normal population. For example, testing for the mean like we have considered say,  $X_1, X_2, X_n$  a random sample from say normal  $\mu$   $\sigma^2$ .

Then, we have considered testing for  $\mu$ , we have also considered testing for variance, we also consider 2 sample problems that means we have say,  $X_1, X_2, X_m$  a random sample from normal  $\mu_1$   $\sigma_1^2$  and  $Y_1, Y_2, Y_n$  a random sample from another normal population say normal  $\mu_2$   $\sigma_2^2$ . So, we have considered equality of means; equality of means and variances etc.

So, we have considered various testing situations for example, testing for  $\mu$  and  $\sigma^2$  is known, testing for  $\mu$  and  $\sigma^2$  is unknown, we have considered testing for  $\sigma^2$ , again when  $\mu$  is known or unknown. We also found the confidence intervals for these parameters in these situations. In the 2 sample problems, we considered testing for  $\mu_1 < \text{or} = \mu_2$ ,  $\mu_1 > \mu_2$  etc., and similarly for  $\sigma_1^2 = \sigma_2^2$ ,  $\sigma_1^2 < \sigma_2^2$  etc.

We have seen that these tests are based on normal chi square t and f distributions. Now, in the multivariate situation, let us consider these. Of course, we also considered the confidence interval in all the situations and they were also dependent upon these distributions. So, now we consider the multivariate analogue of this testing and confidence interval problems. So, let us consider; we will consider testing and confidence interval for parameters of a multivariate normal population.

**(Refer Slide Time: 03:40)**

So, let me introduce 1 sample problem first. So, we will assume that we have a random sample; let  $X_1, X_2, \dots, X_n$  be a random sample from  $N_p(\mu, \Sigma)$  population. So, let us consider  $\Sigma$  is known, so we can; let us consider say, testing for  $\mu$ , so we want to test whether the mean vector  $\mu$  is = a known vector  $\mu_0$  against  $\mu$  is not =  $\mu_0$ , we consider the structure of the sufficient statistics here,  $\bar{X}$ ;  $\bar{X}$  follows  $N_p(\mu, \frac{1}{n} \Sigma)$ .

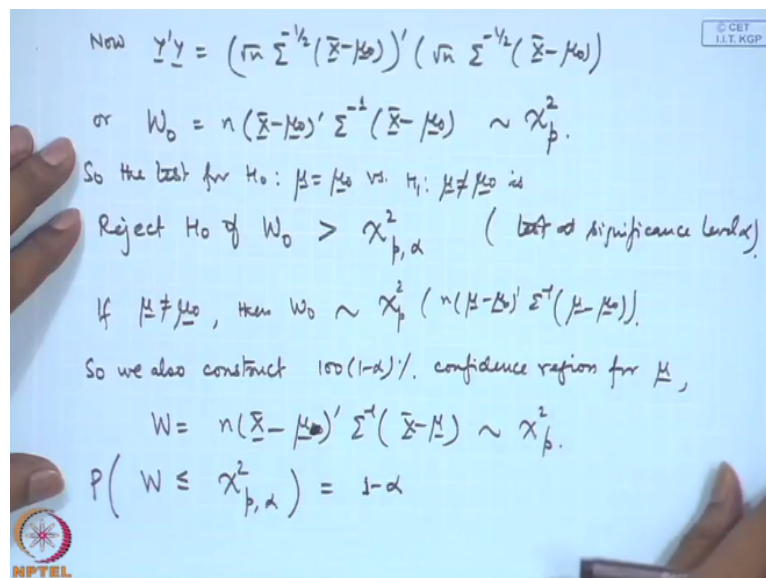

So, based on this we can define  $\sqrt{n}(\bar{X} - \mu_0)$ ; so for example, if I consider  $\sqrt{n}(\bar{X} - \mu_0)$  that will have  $N_p(0, \Sigma)$  and then if I consider  $\sqrt{n} \Sigma^{-1/2}(\bar{X} - \mu_0)$

that will have  $N(\mu, \Sigma)$ . Now, that means, we are assuming here  $\Sigma$  is known and positive definite, we are assuming it is positive definite, so that inverse is defined and we have already discussed in detail then that how to define  $\Sigma$  to the power  $-1/2$  matrix.

That means we consider the spectral decomposition of  $\Sigma$  as  $P, D, P^T$ , where  $D$  is a diagonal matrix and then we consider  $\Sigma$  to the power  $1/2$  as  $PD$  to the power  $1/2 P^T$  and  $\Sigma$  to the power  $-1/2$  can now again we obtained as  $PD$  to the power  $-1/2 P^T$  etc., so all these things can be determined for a positive definite matrix. Now, the components of this become independent standard normal random variables.

That is components; let us call it say,  $Y$ ; components of  $Y$  are independent standard normal random variables, then  $Y^T Y$ , suppose  $I$  am writing say,  $Y = Y_1, Y_2, \dots, Y_n$  that is  $Y^T$  is the row vector, then  $Y^T Y$  that is  $\sum Y_i^2$  that will follow chi square distribution on  $p$  degrees of freedom. These will be  $p$  components because we are dealing with the  $p$  dimensional normal distribution.

**(Refer Slide Time: 07:33)**

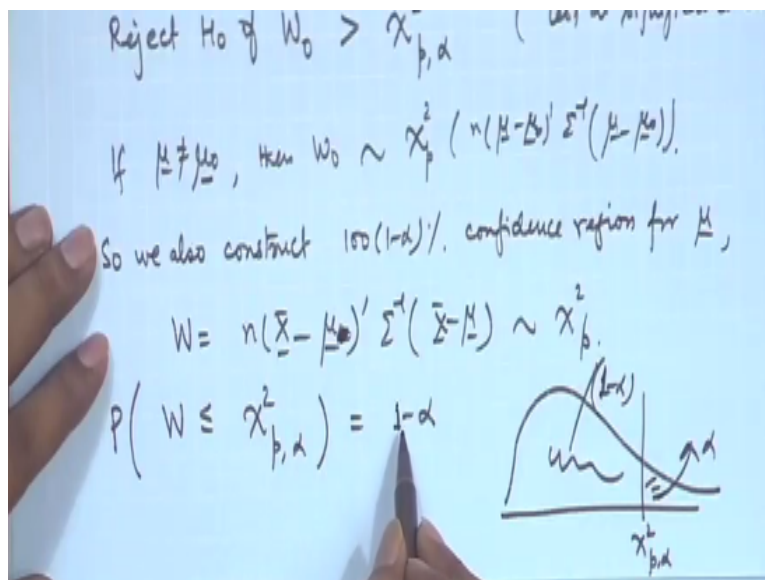

So,  $Y^T Y$  that is  $\sum Y_i^2$  will have a chi square distribution on  $p$  degrees of freedom, so if that is so; let us write  $Y^T Y$ . So, now what is  $Y^T Y$ ? That will become = square root  $n$   $\Sigma$  to the power  $-1/2$   $\bar{X} - \mu_0$  prime root  $n$   $\Sigma$  to the power  $-1/2$   $\bar{X} - \mu_0$  that is =  $n$  times  $\bar{X} - \mu_0$  prime  $\Sigma$  to the power  $-1$   $\bar{X} - \mu_0$ , then that will follow chi square distribution on  $p$  degree of freedom.

So, now based on this we can consider the test for  $\mu = \mu_0$ , when  $\mu = \mu_0$ , we are getting this, then  $\mu = \mu_0$ , then we have this distribution. So, the test for  $H_0: \mu = \mu_0$  against  $\mu \neq \mu_0$  is reject  $H_0$ , if this value; let us call it  $W_0$ ;  $W_0 > \chi^2_{p, \alpha}$  at significance level  $\alpha$ . Now, we can also consider based on this, see here what we are getting is that we are assuming  $\mu = \mu_0$ .

If  $\mu \neq \mu_0$  and then if I consider the distribution of  $W_0$ , then that will be non-central chi square with non-centrality parameter  $\mu - \mu_0$  prime sigma inverse  $\mu - \mu_0$ , so we can also construct  $1 - \alpha$ ;  $100(1-\alpha)$  % confidence region for  $\mu$ . If I consider say,  $W = n(\bar{X} - \mu_0)' \Sigma^{-1} (\bar{X} - \mu_0)$ , then that is having chi square  $p$ , so I can write probability of  $W \leq \chi^2_{p, \alpha}$  that is  $= 1 - \alpha$ .

**(Refer Slide Time: 10:51)**

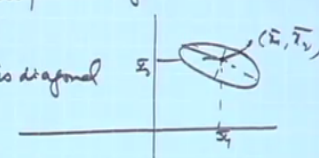

So, because if I consider this region chi square  $p$  alpha, this is the point, this probability is  $\alpha$ , so this probability is  $1 - \alpha$ . So, if I consider this portion, then now here I consider the set of those  $\mu$ 's for which this is satisfied.

**(Refer Slide Time: 11:17)**

So  $P\left(\left\{ \mu: n(\bar{X}-\mu)' \Sigma^{-1}(\bar{X}-\mu) \leq \chi^2_{p,\alpha} \right\} \right) = 1-\alpha$   
 $\mu \in \mathbb{R}^p$ . 100(1- $\alpha$ )% confidence region

This gives a p-dimensional ellipsoidal region in  $\mathbb{R}^p$ .

Special case say  $p=2$ , &  $\Sigma$  is diagonal  
 $\Sigma = \begin{pmatrix} \sigma_1^2 & 0 \\ 0 & \sigma_2^2 \end{pmatrix}$

$n(\bar{x}_1 - \mu_1, \bar{x}_2 - \mu_2) \begin{pmatrix} \frac{1}{\sigma_1^2} & 0 \\ 0 & \frac{1}{\sigma_2^2} \end{pmatrix} \begin{pmatrix} \bar{x}_1 - \mu_1 \\ \bar{x}_2 - \mu_2 \end{pmatrix} \leq \chi^2_{p,\alpha}$

$n\left(\frac{(\bar{x}_1 - \mu_1)^2}{\sigma_1^2} + \frac{(\bar{x}_2 - \mu_2)^2}{\sigma_2^2}\right) \leq \chi^2_{p,\alpha}$        $\frac{(\bar{x}_1 - \mu_1)^2}{\sigma_1^2 \chi^2_{p,\alpha}/n} + \frac{(\bar{x}_2 - \mu_2)^2}{\sigma_2^2 \chi^2_{p,\alpha}/n} \leq 1$

So, if I consider probability of the region, the set of all those  $\mu$ 's for which  $n(\bar{X} - \mu)' \Sigma^{-1}(\bar{X} - \mu) \leq \chi^2_{p,\alpha}$ , then this is  $= 1 - \alpha$ , where  $\mu$  is vector in the  $p$  dimension. So, this gives a  $p$  dimensional ellipsoidal region in  $\mathbb{R}^p$ , so this is called 100(1- $\alpha$ )% confidence region. So, basically this is the interior and the boundary of the space. So, for example, if I consider 2 dimension, it may become something like this.

Suppose, this is my say,  $x_1, x_2$  vector, so this is say; this point is say  $\bar{X}_1, \bar{X}_2$  and then you have this, so you are getting the components of this. Let us take say, special case say,  $p = 2$  and  $\Sigma$  is a diagonal that is say,  $\Sigma = \begin{pmatrix} \sigma_1^2 & 0 \\ 0 & \sigma_2^2 \end{pmatrix}$ , then how this region will look like? This will become  $n(\bar{X}_1 - \mu_1)^2 / \sigma_1^2 + n(\bar{X}_2 - \mu_2)^2 / \sigma_2^2 \leq \chi^2_{p,\alpha}$ .

So, this quantity can be easily calculated, it is  $= n$  times; now if I multiply, I will get  $(\bar{X}_1 - \mu_1)^2 / \sigma_1^2 + (\bar{X}_2 - \mu_2)^2 / \sigma_2^2 \leq \chi^2_{p,\alpha} / n$ , so this is can be easily seen that what is a ellipse here. Here, the centre is  $\bar{X}_1, \bar{X}_2$  and you are also getting, if I divide by this here,  $(\bar{X}_1 - \mu_1)^2 / (\sigma_1^2 \chi^2_{p,\alpha} / n) + (\bar{X}_2 - \mu_2)^2 / (\sigma_2^2 \chi^2_{p,\alpha} / n) \leq 1$ .

**(Refer Slide Time: 14:28)**

$$n \begin{pmatrix} \bar{x}_1 - \mu_1 \\ \bar{x}_2 - \mu_2 \end{pmatrix}' \begin{pmatrix} \frac{1}{\sigma_1^2} & 0 \\ 0 & \frac{1}{\sigma_2^2} \end{pmatrix} \begin{pmatrix} \bar{x}_1 - \mu_1 \\ \bar{x}_2 - \mu_2 \end{pmatrix} \leq \chi_{p, \alpha}^2$$

$$n \left( \frac{(\bar{x}_1 - \mu_1)^2}{\sigma_1^2} + \frac{(\bar{x}_2 - \mu_2)^2}{\sigma_2^2} \right) \leq \chi_{p, \alpha}^2 \quad \frac{(\bar{x}_1 - \mu_1)^2}{\sigma_1^2 \chi_{p, \alpha}^2 / n} + \frac{(\bar{x}_2 - \mu_2)^2}{\sigma_2^2 \chi_{p, \alpha}^2 / n} \leq 1$$

This is the interior of the ellipse with centre  $(\bar{x}_1, \bar{x}_2)$  & major axis is  $a = \sigma_1^2 \chi_{p, \alpha}^2 / n$   
 $b = \sigma_2^2 \chi_{p, \alpha}^2 / n$ .

So, this is the interior of the ellipse with centre  $\bar{x}_1, \bar{x}_2$  and major axis is = twice sigma 1 chi; so let us write, you are having, a square that is = sigma 1 square chi square p alpha/n and for minor axis, you are getting b, so b Square is here = sigma 2 square chi square p alpha/ n. So, you can easily plot the region and see how the ellipse will look like. So, we are able to solve this 1 sample problem, when the variance covariance matrix is assumed to be known.

**(Refer Slide Time: 15:58)**

Two Sample Problem

Let  $X_1, \dots, X_m$  be a random sample from  $N_p(\mu_1, \Sigma)$   
and let  $Y_1, \dots, Y_n$  be another independent random sample from  
 $N_p(\mu_2, \Sigma)$ .  $\Sigma$  known & positive definite.

$$\bar{X} \sim N_p(\mu_1, \frac{1}{m} \Sigma), \quad \bar{Y} \sim N_p(\mu_2, \frac{1}{n} \Sigma).$$

$$\bar{X} - \bar{Y} \sim N_p(\mu_1 - \mu_2, (\frac{1}{m} + \frac{1}{n}) \Sigma). \quad \underline{v} = \mu_1 - \mu_2.$$

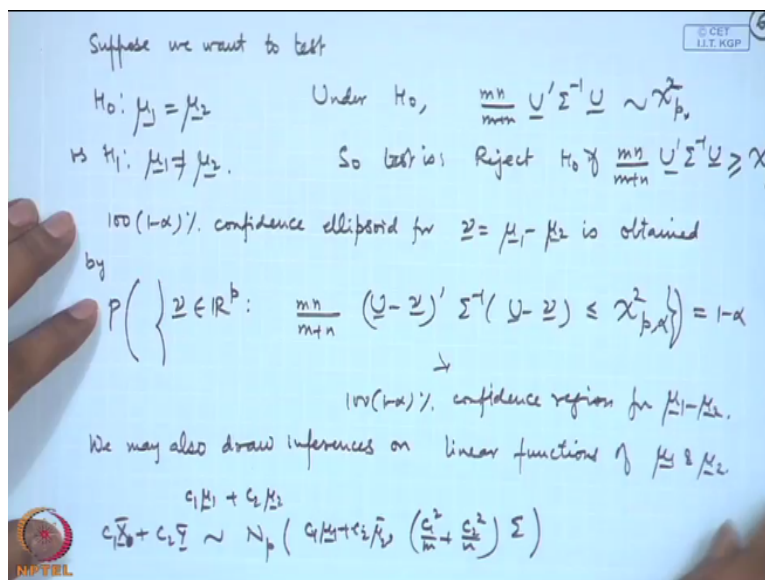

$$\frac{mn}{m+n} (\underline{U} - \underline{v})' \Sigma^{-1} (\underline{U} - \underline{v}) \sim \chi_p^2$$

where  $\underline{v} = \mu_1 - \mu_2$ .

So, we are actually making use of the central chi square distribution. When the variance covariance matrix is known, we can also write down confidence region or the test for equality of means in the 2 population case or the 2 sample problem. So, let me consider 2 sample problem and so let us consider, let  $X_1, X_2, X_n$  be a random sample from  $N_p \mu_1 \sigma$  distribution.

And let,  $Y_1, Y_2, \dots, Y_n$  be another independent random sample from  $N_p(\mu_2, \Sigma)$  population, here again I am assuming  $\Sigma$  is known and positive definite. Let us consider say,  $\bar{X}$ , so that will have normal  $N_p(\mu_1, \Sigma/m)$ , if I consider  $\bar{Y}$  that will have  $N_p(\mu_2, \Sigma/n)$ . So, let us work out the distribution theory here,  $\bar{X} - \bar{Y}$  that will be  $N_p(\mu_1 - \mu_2, \Sigma(1/m + 1/n))$ , so we can call this  $\mu$  that is  $= \mu_1 - \mu_2$ .

**(Refer Slide Time: 18:45)**

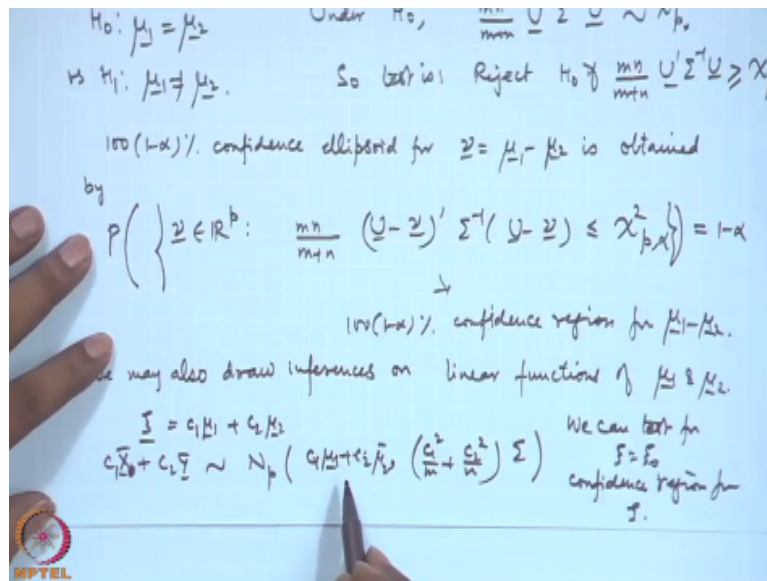

So, we can then write here, this is becoming  $m + n/mn$ , so we can write then,  $mn/m + n, U - \mu$ ; say,  $N_p(\mu, \Sigma^{-1} U - \mu)$  that will have chi square distribution on  $p$  degrees of freedom, where I am defining this  $U$  is  $=$  the difference of  $\bar{X} - \bar{Y}$  and  $\mu$  is  $= \mu_1 - \mu_2$ . Therefore, this can be used for trying inference on  $\mu_1 - \mu_2$ . For example, if I want to do the testing, suppose we want to test say,  $H_0: \mu_1 = \mu_2$  against say,  $H_1: \mu_1 \neq \mu_2$ .

So, under  $H_0$ , you will have  $mn/m + n, U - \Sigma^{-1} U$ ; sorry,  $U' \Sigma^{-1} U$  that will follow chi square  $p$  distribution. So, test is reject  $H_0$ , if this quantity  $mn/m + n, U' \Sigma^{-1} U$  is  $>$  or  $=$  chi square  $p, \alpha$  and we can also construct the confidence in region,  $100(1 - \alpha)\%$  confidence, again it will be ellipsoid only; ellipsoid for  $\mu$  is  $= \mu_1 - \mu_2$  that will be; if I consider probability of say,  $\mu$  belonging to  $R^p, mn/m + n, U' \Sigma^{-1} U <$  or  $=$  chi square  $p, \alpha$ , this is  $= 1 - \alpha$ .

If I consider this region in the  $p$  dimensional Euclidean space, so this is  $100(1 - \alpha)\%$  confidence region for  $\mu_1 - \mu_2$ . One can actually also write for some linear combinations also, we may also draw inferences on linear functions of  $\mu_1$  and  $\mu_2$ . For example, I

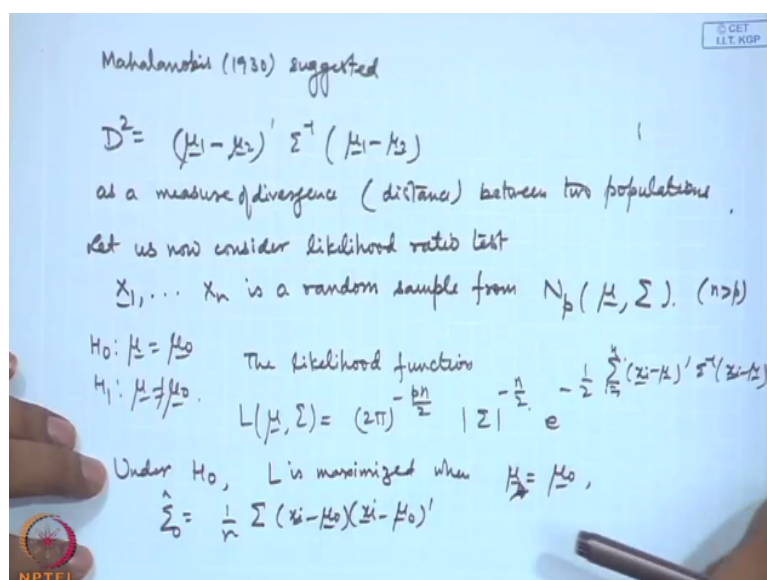

consider say, some  $c_1 \mu_1 + c_2 \mu_2$ , then I can consider say,  $c_1 \bar{X}$ ;  $c_1 \bar{X} + c_2 \bar{y}$ , then that will have  $N_p$  and we can write down the distribution here.

(Refer Slide Time: 22:29)

We can also consider linear combination of the components of  $\mu_1$  and  $\mu_2$  that also we can consider, so for example here it will become  $c_1 \mu_1 + c_2 \mu_2$  and here I will get  $c_1^2/m + c_2^2/n$  sigma. So, based on this, again we can construct test and confidence interval for  $c_1 \mu_1 + c_2 \mu_2$ , suppose I call it  $X_i$ , so we can test for  $X_i = X_{i0}$  or we can find confidence intervals or confidence region for  $X_i$ .

(Refer Slide Time: 23:15)

So, again it will be in the terms of chi square  $p$  distribution that is the central chi square distribution that we will be getting here. Actually this idea for making use of  $\bar{X} - \mu$ , this term actually the initial ideas are hidden in the Mahalanobis  $D$  square statistic. So, let me just

mention that thing. He suggested using D square that is  $\mu_1 - \mu_2$  prime sigma inverse  $\mu_1 - \mu_2$  as a measure of; he called it divergence or distance basically between 2 populations.

Let us also consider the general situations here say, likelihood ratio test, so again  $X_1, X_2, \dots, X_n$  is a random sample from  $N_p(\mu, \Sigma)$  and of course, we assume as usual  $n > p$  and we are considering  $\mu = \mu_0$  against  $\mu \neq \mu_0$ . The likelihood ratio criteria involve the likelihood function, so we calculate the likelihood function here;  $(2\pi)^{-np/2}$  determinant of sigma to the power  $-n/2$ ,  $e^{-\frac{1}{2} \sum (x_i - \mu)' \Sigma^{-1} (x_i - \mu)}$  inverse  $x_i - \mu$ .

**(Refer Slide Time: 26:10)**

So the maximum of the likelihood fn. under  $H_0$  is

$$\hat{L}_0 = (2\pi)^{-np/2} |\hat{\Sigma}_0|^{-n/2} e^{-\frac{1}{2} \sum (x_i - \mu_0)' \hat{\Sigma}_0^{-1} (x_i - \mu_0)}$$

↓

$$\begin{aligned} & \text{tr} \sum (x_i - \mu_0)' \hat{\Sigma}_0^{-1} (x_i - \mu_0) \\ &= \text{tr} \sum \hat{\Sigma}_0^{-1} (x_i - \mu_0) (x_i - \mu_0)' \\ &= \text{tr} \hat{\Sigma}_0^{-1} \sum (x_i - \mu_0) (x_i - \mu_0)' \\ &= n \text{tr} \hat{\Sigma}_0^{-1} \hat{\Sigma}_0 \\ &= np. \end{aligned}$$

So  $\hat{L}_0 = (2\pi)^{-np/2} |\hat{\Sigma}_0|^{-n/2} e^{-np/2}$ .

Now, under  $H_0$ , this  $L$  is maximised, then  $\mu = \mu_0$  because under  $H_0$   $\mu = \mu_0$  and sigma will be considered as; so let us put  $\mu_0$  here and sigma 0 that will be  $= 1/n \sum (x_i - \mu_0) (x_i - \mu_0)'$ . So, the maximum of the likelihood function under  $H_0$  is; let us call it  $L_0$  that is  $= (2\pi)^{-np/2}$  determinant of sigma 0 head to the power  $-n/2$  and if I consider this term here;  $e^{-1/2 \sum (x_i - \mu_0)' \Sigma_0^{-1} (x_i - \mu_0)}$  inverse  $x_i - \mu_0$ .

Now, if you look at this term, this is actually a scalar term; this term is a scalar, so we can also consider it as trace of this term. Now, this I can write as trace of sigma, sigma 0 head inverse  $\sum (x_i - \mu_0) (x_i - \mu_0)'$ ;  $\sum (x_i - \mu_0) (x_i - \mu_0)'$ . Now, this sigma I can take inside, so it becomes trace of sigma 0 head inverse sigma  $\sum (x_i - \mu_0) (x_i - \mu_0)'$  transpose but this is nothing but sigma 0, so this is becoming sigma 0 head inverse, sigma 0 head \* n.

**(Refer Slide Time: 28:25)**

When we consider  $\mu \in \mathbb{R}^p$ ,  $\Sigma$  is  $p \times p$  p.d. matrix, then the maximization of  $L$  gives  $\hat{\mu} = \bar{x}$ ,  $\hat{\Sigma} = \frac{1}{n} \sum (x_i - \bar{x})(x_i - \bar{x})'$

So  $L = (2\pi)^{-np/2} |\hat{\Sigma}|^{-n/2} e^{-np/2}$

So the likelihood ratio  $\lambda = \frac{L_0}{L} = \left( \frac{|\hat{\Sigma}|}{|\hat{\Sigma}_0|} \right)^{n/2}$

$\lambda = \frac{|\hat{\Sigma}|}{|\hat{\Sigma}_0|} = \left\{ \frac{|S|}{|S + n(\bar{x} - \mu_0)(\bar{x} - \mu_0)'|} \right\}$

So, this is becoming  $np$ , so  $L_0$  head is becoming  $2\pi$  to the power  $-np/2$  determinant of sigma head to the power  $-n/2$   $e$  to the power  $-np/2$ , Now, under the full space, then we consider  $\mu$  belonging to  $\mathbb{R}^p$  and sigma is a  $p/p$  positive definite matrix, then the maximization of  $L$  gives  $\mu$  head is  $= \bar{X}$  and sigma head is  $= \frac{1}{n} \sum (x_i - \bar{x})(x_i - \bar{x})'$ . Once again, if I put  $L$  head that is  $= 2\pi$  to the power  $-np/2$  determinant of sigma to the power; sigma head to the power  $-1/2$ ,  $e$  to the power  $-np/2$ .

So, this will be same part here, so the likelihood ratio that we consider that is  $L_0$  head/  $L$  head that is  $=$ ; so if you look at these terms here,  $L_0$  head and  $L$  head, then these 2 things are common; these two terms are common, so this will get cancelled out, you are left with only determinant of sigma 0 head and determinant of sigma head and this is  $-1/2$ , I am sorry; this is  $-n/2$  here, so this will be  $-n/2$  and this will become  $-n/2$ .

**(Refer Slide Time: 31:00)**

$$\hat{L} = (2\pi)^{-n/2} |\hat{\Sigma}|^{-1/2} e^{-\frac{1}{2}(\bar{x} - \mu_0)' \hat{\Sigma}^{-1} (\bar{x} - \mu_0)}$$

So the likelihood ratio  $\lambda = \frac{\hat{L}_0}{\hat{L}} = \left( \frac{|\hat{\Sigma}|}{|\hat{\Sigma}_0|} \right)^{n/2}$

$$\lambda^{2/n} = \frac{|\hat{\Sigma}|}{|\hat{\Sigma}_0|} = \left\{ \frac{|S|}{|S + n(\bar{x} - \mu_0)(\bar{x} - \mu_0)'|} \right\}$$

or  $\lambda^{2/n} = \frac{1}{1 + n(\bar{x} - \mu_0)' S^{-1} (\bar{x} - \mu_0)} = \frac{1}{1 + T^2/(n-1)} = \frac{1}{1 + T^2/k}$

So the LRT is Reject  $H_0$  when  $\lambda \leq \lambda_0$

So, this is now I am getting determinant of sigma head/ determinant of sigma 0 head to the power n/2, let us call it say, lambda. So, lambda to the power 2/ n that is = determinant of sigma head divided by determinant of sigma. Now, this is nothing but S here; divided by S + n times x bar – Mu0, x0 – Mu0 prime or we can consider lambda to the power 2/n, this will become = 1/ 1+ n x bar – Mu0 prime S inverse x0 – Mu0, which is nothing but 1/ 1 + T square/ n - 1 that is 1/ 1 + T square/ k.

**(Refer Slide Time: 31:58)**

$$\text{or } \frac{1}{1 + T^2/k} \leq c_0$$

$$\text{or } T^2 \geq T_0^2$$

If we take confidence level to be  $\alpha$ , then

$$T_0 = \frac{(n-1)p}{n-p} F_{p, n-p, \alpha} = T^2_{p, n-1, \alpha}$$

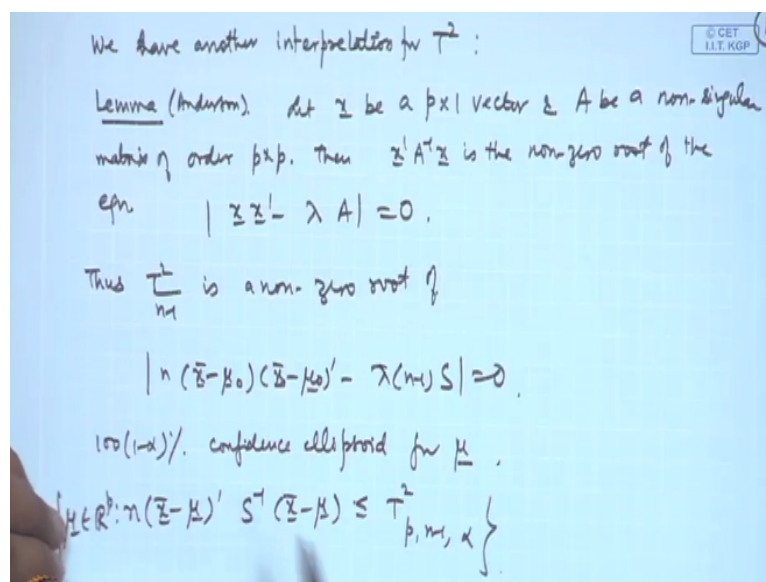

To compute  $T^2$  we need not find directly  $S^{-1}$ . Instead we can consider  $\underline{b}$  as the solution vector of the system of linear equations,  $S \underline{b} = \bar{x} - \mu_0$  and then  $T^2 = n(n-1) (\bar{x} - \mu_0)' \underline{b}$ .

This T square/ k, this term I introduced in the last class, which is coming from the Hotelling's T square distribution, so the likelihood ratio test is reject  $H_0$ , when lambda is < or = some lambda 0, 1/ 1 + T square/ k < or = some c0 or we can say, T square > or = some T0 square. If we take confidence level to be alpha then, T0 we can choose to be n – 1 p/ n – p, F on p, n - p alpha, this value actually we will call the percentage point of the Hotelling's T square distribution.

Here, 1 computational problem is there that is; if the data is given to you, you need to evaluate this T square here that is  $\bar{x} - \mu_0' S^{-1} (\bar{x} - \mu_0)$ ; this involves the evaluation of the inverse of S, which may be quite complicated. For example, if you have  $p = 4$  or  $p = 5$ , then this is quite complicated exercise but one can actually do it by using numerical techniques, you consider it as a solution of the simultaneous linear equations.

Let me just present a method here. To compute T square, we need not find directly S inverse, instead we can consider b as the solution vector of the system of linear equations that is  $Sb = \bar{x} - \mu_0$  and then T square is nothing but  $n^{-1} (\bar{x} - \mu_0)' S^{-1} (\bar{x} - \mu_0)$ . So, one can use some numerical technique like Gauss elimination backward etc., all those things can be used for solving this system.

**(Refer Slide Time: 34:42)**

There is another interpretation to this, here we have another interpretation for T square, let me firstly state a Lemma, which is from Anderson, let  $x$  be a  $p \times 1$  vector and  $A$  be a non-singular matrix of order  $p \times p$ , then  $x' A^{-1} x$  is the nonzero root of the equation  $x x' - \lambda A = 0$ . If I use this, then I can say that  $T^2 / n - 1$  is a nonzero root of  $n(\bar{x} - \mu_0)' S^{-1} (\bar{x} - \mu_0) - \lambda(n-1) = 0$ .

Similarly, the  $1 - \alpha$  confidence region; so here we will have, 100(1- $\alpha$ ) % confidence ellipsoid for  $\mu$ , this will be  $n(\bar{x} - \mu)' S^{-1} (\bar{x} - \mu) \leq T^2_{p, n-1, \alpha}$ . The set of all the  $\mu$ 's in  $R^p$  satisfying this condition, this set is the confidence region for  $\mu$  here. As we have given the interpretation earlier, this is ellipsoid in the higher

dimensional space. One can also actually find out, as I mentioned a little earlier that we can consider linear combinations of vectors.

**(Refer Slide Time: 37:45)**

Simultaneous Confidence Regions for All linear Combinations of a mean vector

For a positive definite matrix  $S$

$$(\underline{y}'\underline{y})^2 \leq (\underline{y}'S\underline{y})(\underline{y}'S^{-1}\underline{y}).$$

pf. Let  $b = \frac{\underline{y}'\underline{y}}{\underline{y}'S\underline{y}}$ .

$$(\underline{y} - bS\underline{y})'S^{-1}(\underline{y} - bS\underline{y})$$

$$= \underline{y}'S^{-1}\underline{y} - \frac{(\underline{y}'\underline{y})^2}{\underline{y}'S\underline{y}} \geq 0.$$

So, for example here I mentioned that we can consider  $c_1 \mu_1 + c_2 \mu_2$  etc, we can consider more than 1 also that means, we can consider simultaneous confidence intervals for all linear combinations of a mean vector. So, that also we can give; let me just briefly mention about that also here. For all linear combinations of a mean vector, we first have the following result that for a positive definite matrix  $S$ ,  $\gamma' y^2$  is  $<$  or  $=$   $\gamma' S \gamma$ ,  $y' S^{-1} y$ .

Let us look at the proof here, let us consider say,  $b$  to be  $\gamma' y$  divided by  $\gamma' S \gamma$ . Now, if I consider  $y - bS \gamma$ , this is a scalar here. Now, if I expand this, I can get it as  $= y' S^{-1} y - \gamma' y^2 / \gamma' S \gamma$ , now this is  $>$  or  $= 0$ , so this gives the result here. This is basically you can consider as a generalization of the Cauchy Schwarz inequality to higher dimensions.

**(Refer Slide Time: 39:39)**

$$= \underline{y}' S^{-1} \underline{y} - \frac{(\underline{y}' \underline{1})^2}{\underline{1}' S \underline{1}} \geq 0.$$

Put  $\underline{y} = \bar{x} - \mu$  in the above, we get

$$|\underline{y}'(\bar{x} - \mu)| \leq \left\{ (\underline{y}' S \underline{y}) (\bar{x} - \mu)' S^{-1} (\bar{x} - \mu) \right\}^{1/2}$$

$$\leq (\underline{y}' S \underline{y}) \left( \frac{F_{p, n-p, \alpha}^2}{n} \right)^{1/2} \quad \text{w.p.}(1-\alpha)$$

So, if I substitute say,  $y$  is  $= \bar{X} - \mu$ , then we get  $\gamma' x - \mu$  is  $< \text{or} = \gamma' S \gamma x \bar{\mu} S^{-1} x \bar{\mu} - \mu$  to the power  $1/2$  but if we use the distribution of this, then this is nothing but  $\gamma' S \gamma T^2 p n - 1 \alpha$  divided by  $n$  to the power  $1/2$ , this is true with probability  $1 - \alpha$ , so we are getting that all linear combinations here, they will satisfy simultaneous inequalities of the form.

**(Refer Slide Time: 40:46)**

$$\left| \underline{r}' \bar{x} - r' \mu \right| \leq (\underline{r}' S \underline{r})^{1/2} \left( \frac{F_{p, n-p, \alpha}^2}{n} \right)^{1/2}$$

Two Sample Problem when  $\Sigma$  is unknown.

Let  $\underline{y}_1^{(1)}, \dots, \underline{y}_{n_1}^{(1)} \stackrel{i.i.d.}{\sim} N_p(\mu^{(1)}, \Sigma)$

$\underline{y}_1^{(2)}, \dots, \underline{y}_{n_2}^{(2)} \stackrel{i.i.d.}{\sim} N_p(\mu^{(2)}, \Sigma)$  }  $\Sigma$  is common.

$H_0: \mu^{(1)} = \mu^{(2)}$

$H_1: \mu^{(1)} \neq \mu^{(2)}$

That is  $\gamma' x - \gamma' \mu < \text{or} = \gamma' S \gamma$  to the power  $1/2 T^2 p n - 1 \alpha$  divided by  $n$  to the power  $1/2$ , so simultaneously these are satisfied here. So, we have considered 1 sample problem for  $\mu$ , when  $\Sigma$  is known and also we have resolved the problem, when  $\Sigma$  is unknown. We have considered the 2 sample problem, when  $\Sigma$  is known.

Now, let us consider 2 sample problem, when sigma is unknown, here again as before we have 2 cases; 1 case in which the variance covariance matrix is considered to be common and in another case, we will consider it to be uncommon and the procedures will be different as you had seen in the case of univariate problem. So, let us consider the 2 sample problem, then sigma is; now when sigma is unknown, so we are actually considering; I am just a little bit modifying the notations here.

So, let us consider say, we write in terms of  $y$  itself just because we will consider a generalization to higher dimensions also and that means multi sample also, so if I consider  $y_{1,1}$  and so on,  $y_{n1}$ , so this is a random sample from  $N_p \mu_1 \sigma$ , so these are independent and identically distributed and similarly I consider  $y_{1,2}$  and so on,  $y_{n2}$ , this is a random sample from  $\mu_2 \sigma$ .

So, these 2 are same, sigma is common but unknown and now as before we will be testing equality of the mean vectors. Let me mention here that we have considered the problems in which the testing problem is about the equality or not, in the case of univariate we had seen other kind of testing problems also like  $\mu_1 < \text{or} = \mu_2$  or  $\mu_1 > \mu_2$  etc., but here I am not giving those procedures here.

In fact, if we consider inequalities, then there can be various cases for example, first component may be less, second component may be more, third component may be equal, so you can have various kind of hypothesis testing problems. Some of the popular ones are like ordered alternatives we call, in which the concept of isotonic regression is used, so there are many research papers currently available on that topic both for the known and unknown variance cases.

**(Refer Slide Time: 44:30)**

Two Sample Problem when  $\Sigma$  is unknown.

Let  $y_1^{(1)}, \dots, y_{n_1}^{(1)} \stackrel{i.i.d.}{\sim} N_p(\mu^{(1)}, \Sigma)$   
 $y_1^{(2)}, \dots, y_{n_2}^{(2)} \stackrel{i.i.d.}{\sim} N_p(\mu^{(2)}, \Sigma)$  }  $\Sigma$  is common.

$H_0: \mu^{(1)} = \mu^{(2)}$        $\bar{y}_i^{(i)} \sim N_p(\mu^{(i)}, \frac{1}{n_i} \Sigma),$   
 $H_1: \mu^{(1)} \neq \mu^{(2)}$        $i=1, 2$

$\sqrt{\frac{n_1 n_2}{n_1 + n_2}} (\bar{y}^{(1)} - \bar{y}^{(2)}) \sim N_p(0, \Sigma)$

In this particular course, we will discuss only the basic ones that means the equality concept is being tested here. So, we will construct the Hotelling's T square here, so let us consider the sample mean vectors;  $\bar{y}_1$  that will be  $N_p(\mu^{(1)}, \frac{1}{n_1} \Sigma)$ , for  $i = 1, 2$ . So, if I consider the difference square root  $\sqrt{\frac{n_1 n_2}{n_1 + n_2}} (\bar{y}_1 - \bar{y}_2)$  that will follow  $N_p(0, \Sigma)$ . Now, in this case  $\Sigma$  is unknown, so we make use of  $S$ , now.

(Refer Slide Time: 45:27)

We consider sample dispersion matrices

$$S_i = \sum_{j=1}^{n_i} (y_j^{(i)} - \bar{y}^{(i)}) (y_j^{(i)} - \bar{y}^{(i)})', \quad i=1, 2.$$

Then  $S_1 + S_2$  is distributed as  $\sum_{k=1}^{n_1+n_2-2} z_k z_k'$

where  $z_k \sim N(0, \Sigma)$ .

$$S = \frac{1}{n_1 + n_2 - 2} (S_1 + S_2)$$

And for  $S$ , we have 2 things like from the first sample, we will get the variance covariance matrix as  $S_1$  and from the second, I will get variance covariance matrix as  $S_2$  and then we will consider pooling of that, so let us define this. We consider sample dispersion matrices, so that is  $S_1$  that is  $= \sum_{j=1}^{n_1} (y_j^{(1)} - \bar{y}^{(1)}) (y_j^{(1)} - \bar{y}^{(1)})'$ ,  $j$  is  $= 1$  to  $n_1$ , so if I put here  $n_1$  and here I put  $i$  and this is I can call  $i$ ;  $i = 1, 2$ .

(Refer Slide Time: 47:08)

Then  $S_1 + S_2$  is distributed as  $\sum_{k=1}^{n_1+n_2-2} z_k z_k'$

where  $z_k \sim N(0, \Sigma)$ .

$$S = \frac{1}{n_1 + n_2 - 2} (S_1 + S_2)$$

$$T^2 = \frac{n_1 n_2}{n_1 + n_2} (\bar{y}^{(1)} - \bar{y}^{(2)})' S^{-1} (\bar{y}^{(1)} - \bar{y}^{(2)})$$

Rejection region is  $T^2 > \frac{(n_1 + n_2 - 2) p}{(n_1 + n_2 - p - 1)} F_{p, n_1 + n_2 - p - 1, \alpha}$

And we can consider  $S_1 + S_2$ , then this is having the same distribution,  $\sigma z_k$ ,  $z_k$  transpose,  $k = 1$  to  $n_1 + n_2 - 2$ , where  $z_k$  is normal  $0, \sigma$ , so we define  $S$  is  $= 1/n_1 + n_2 - 2 \sigma_1 + \sigma_2$ ; sorry  $S_1 + S_2$ , then based on this we can define the Hotelling's T square that is  $n_1 n_2 / (n_1 + n_2) (\bar{y}_1 - \bar{y}_2)' S^{-1} (\bar{y}_1 - \bar{y}_2)$ . Then, this has a Hotelling's T square distribution on  $n_1 + n_2 - 2$  degrees of freedom.

(Refer Slide Time: 48:27)

We can also construct  $100(1-\alpha)\%$  confidence region for  $\mu_1 - \mu_2$

as

$$\left\{ \xi \in \mathbb{R}^p : (\bar{y}^{(1)} - \bar{y}^{(2)} - \xi)' S^{-1} (\bar{y}^{(1)} - \bar{y}^{(2)} - \xi) \leq \frac{n_1 n_2}{n_1 + n_2} T^2_{p, n_1 + n_2 - 2, \alpha} \right\}$$

Simultaneous confidence regions are

$$\left\{ Y' (\bar{y}^{(1)} - \bar{y}^{(2)}) - Y' \xi \leq (Y' S Y)^{1/2} \left\{ \frac{n_1 n_2}{n_1 + n_2} T^2_{p, n_1 + n_2 - 2, \alpha} \right\}^{1/2} \right\}$$

So, if we consider based on the representation in terms of F, so the rejection region is  $T^2 > (n_1 + n_2 - 2) * p / (n_1 + n_2 - p - 1) F_{p, n_1 + n_2 - p - 1, \alpha}$ , so this is level of significance level here will be alpha for this. We can make use of this for constructing the confidence region also for  $\mu_1 - \mu_2$ , we can also construct; it is the set  $y_1 \bar{y} - y_2 \bar{y} - \text{some } X_i S^{-1} y_1 \bar{y} - y_2 \bar{y} - X_i < \text{or } = (n_1 + n_2) / n_1 * T^2_{p, n_1 + n_2 - 2, \alpha}$ .

The set of all  $p$  dimensional vectors, which satisfy this, so this is the  $100(1-\alpha)\%$  confidence ellipsoid for  $\mu_1 - \mu_2$ . We can also write the; of course, this term you can see that this is also equal to  $n_1 + n_2 / n_1 n_2 T^2$  square \*  $n_1 + n_2 - 2p$  divided by  $n_1 + n_2 - p - 1$ ,  $F_{p, n_1 + n_2 - p - 1}$  alpha, so one can evaluate this using the tables of the F distribution. Similarly, the simultaneous confidence intervals can be written,  $\gamma' - \gamma' X_i < \text{or} = \gamma' S \gamma$  to the power  $1/2 n_1 + n_2 / n_1 n_2 T^2$  square  $p n_1 + n_2 - 2$  alpha to the power  $1/2$ .

**(Refer Slide Time: 51:02)**

Fisher (1936), Anderson  
 $X_1 \rightarrow$  sepal length,  $X_2 \rightarrow$  sepal width,  $X_3 \rightarrow$  petal length,  $X_4 \rightarrow$  petal width  
 $n = 50$ .

Iris versicolor (1)      Iris setosa (2)

$$\bar{x}^{(1)} = \begin{pmatrix} 5.936 \\ 2.770 \\ 4.260 \\ 1.326 \end{pmatrix}, \quad \bar{x}^{(2)} = \begin{pmatrix} 5.006 \\ 3.428 \\ 1.462 \\ 0.246 \end{pmatrix}$$

$$98S = \begin{pmatrix} & & & \\ & & & \\ & & & \\ & & & \end{pmatrix}$$

$$\frac{T^2}{98} = 26.334, \quad \frac{T^2}{98} \times \frac{95}{4} = 625.5$$

which is highly significant  $F_{4, 95}(0.01) = 3.52$   
 So  $H_0: \mu^{(1)} = \mu^{(2)}$  will be certainly rejected.

One of the classical examples is given in the Fisher's paper in 1936, in which he considered the 4 variables as sepal length,  $x_2$  as the sepal width,  $x_3$  as the petal length, and  $x_4$  as the petal width and this data I have taken from the book of Anderson and 50 observations were taken on 2 populations; 1 is iris versicolor and another is the iris setosa, the summarized data is  $\bar{x}_1 = 5.936, 2.770, 4.260, 1.326$ , this is the mean vector; sample mean vector based on 50 observations on the iris versicolor trees.

And the  $\bar{x}_2$  vector that is on the 50 random observations taken on iris setosa trees; 5.006, 3.428, 1.462, 0.246 and  $n_1 + n_2 - 2$  is 98S, so that is given here, I am not writing it here. So,  $T^2 / 98$  value turned out to be 26.334, so if we consider  $T^2 / 98 * 95 / 4 = 625.5$ , which is highly significant, if I take  $F_{4, 95}$  at say, 0.01 etc., that is 3.52 only, so naturally; so  $H_0$  that is  $\mu_1 = \mu_2$  will be certainly rejected.

**(Refer Slide Time: 53:44)**

Simultaneous confidence intervals for  $\mu_i - \mu^*$ ,  $i=1, \dots, 4$   
 are also obtained

$0.930 \pm 0.337$   
 $-0.658 \pm 0.265$   
 $-2.798 \pm 0.270$   
 $1.080 \pm 0.1221$

} 0 does not belong to any interval.

$H_0: \sum_{i=1}^k \beta_i \mu_i = \mu^*$   
 $H_1: \neq$

$\beta_1, \dots, \beta_k$  are given scalars.  
 $\mu^*$  is a given vector

$(\sum \beta_i \bar{x}_i - \mu^*)' S^{-1} (\sum \beta_i \bar{x}_i - \mu^*)$   
 $\bar{x}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} x_j^{(i)}$ ,  $S = \frac{1}{\sum (n_i - 1)} \sum \sum (x_j^{(i)} - \bar{x}_i) (x_j^{(i)} - \bar{x}_i)'$

Here, the simultaneous confidence intervals have also been obtained; simultaneous confidence intervals for  $\mu_i - \mu_i^*$  for  $i = 1$  to  $4$ , they are also obtained, so it is something like  $0.930 \pm 0.337$ ,  $-0.658 \pm 0.265$ ,  $-2.798 \pm 0.270$ ,  $1.080 \pm 0.1221$ , you can see that  $0$  does not belong to any interval in fact, this is quite different from  $0$ , this is quite different from zero, this maybe is little bit closer to  $0$ .

So, naturally you can say that the means of the 2 populations are quite different. As I mentioned that one may consider linear combinations also for example, I may consider testing  $H_0: \sum \beta_i \mu_i = \mu^*$  against  $H_1: \neq$ , where  $\beta_1, \beta_2, \beta_k$  are given scalars and  $\mu^*$  is a given vector, then we can construct the statistic  $(\sum \beta_i \bar{x}_i - \mu^*)' S^{-1} (\sum \beta_i \bar{x}_i - \mu^*)$ , where  $\bar{x}_i$  is actually  $\frac{1}{n_i} \sum_{j=1}^{n_i} x_j^{(i)}$  and  $S$  is  $\frac{1}{\sum (n_i - 1)} \sum \sum (x_j^{(i)} - \bar{x}_i) (x_j^{(i)} - \bar{x}_i)'$ .

**(Refer Slide Time: 56:38)**

$$\begin{aligned}
H_0: \sum_{i=1}^k \beta_i \bar{x}^{(i)} &= \mu^* & \beta_1, \dots, \beta_k \text{ are given scalars.} \\
H_1: \mathcal{D} &\neq & \mu^* \text{ is a given vector}
\end{aligned}$$

$$T^2 = c \left( \sum \beta_i \bar{x}^{(i)} - \mu^* \right)' S^{-1} \left( \sum \beta_i \bar{x}^{(i)} - \mu^* \right)$$

$$\bar{x}^{(i)} = \frac{1}{n_i} \sum_{j=1}^{n_i} x_j^{(i)}, \quad S = \frac{1}{\sum (n_i - 1)} \sum \sum (x_j^{(i)} - \bar{x}^{(i)}) (x_j^{(i)} - \bar{x}^{(i)})'$$

$$c = \sum \beta_i^2 / n_i \quad T^2 \sim \frac{\chi^2}{\sum (n_i - 1)}$$

And c is sigma beta i square/ ni, then T Square will follow T square distribution, on sigma ni - 1 degrees of freedom that is Hotelling's T square here, so we can consider rejecting H0 when this value is > T square sigma ni - k here. In the next lecture, I will consider a problem which is based on symmetry; we will also consider the case when sigma 1 and sigma 2 are not assumed to be known.

Now, this case is again like in the case of univariate, we had only approximate procedures, in the multivariate case however, exact procedures can be constructed but then there is a compromise like we may have to ignore some of the observations, so I will be discussing in detail this problem in the following lecture here.
