(Refer Slide Time: 00:19)

So, we were discussing some tests for the 2 sample scale problem. Let me consider now Sukhatme test. So, for this Sukhatme test let me define  $D_{ij}=1$  if  $Y_j < X_i < 0$  or  $0 < X_i < Y_j$  and it is = 0 otherwise. You can see that there is a little bit modification here. So, we are on one side of 0. Like if  $Y_j < X_i < 0$  or if  $Y_j > X_i > 0$ , in both the cases  $Y_j$  is farther away from 0 than the  $X_i$ . So, that is why you can see that this test is different than the Mann-Whitney or this one.

Because it is not simply based on the order of  $X_i$   $Y_j$  but also the positioning from the 0 and we then define the statistics as double summation  $D_{ij}$ ,  $i=1$  to  $m$ ,  $j=1$  to  $n$ . So, what it will mean a small  $t$ . a small  $t$  indicates more 0s among  $D_{ij}$ . That means  $X$ 's are more variable than  $Y$ 's and so  $\theta$  will be  $> 1$  and large  $T$  will indicate, that is  $Y$ 's are more variable than  $X$ 's, that is  $\theta < 1$ .

So, you can see that this is a very, very natural kind of definition that has been taken by Sukhatme. However, let us show the calculations for this. Let us consider say  $\pi_i$  that is the

probability of  $D_{ij}=1$ . In terms of that, we will actually derive the mean and variance etc. of this statistic. So, this is = probability of  $Y_j < X_i < 0$  or  $0 < X_i < Y_j$ . So, that is equal to probability of  $Y_j < X_i < 0$  plus probability of  $0 < X_i < Y_j$  because these are 2 disjointed event, so we can write it as a sum of the probabilities.

**(Refer Slide Time: 03:45)**

$$P(Y_j < X_i < 0) = \int_{-\infty}^0 P(Y_j < x) dF_x(x)$$

$$= \int_{-\infty}^0 G_y(x) dF_x(x)$$

$$P(0 < X_i < Y_j) = \int_0^{\infty} P(Y_j > x) dF_x(x)$$

$$= \int_0^{\infty} (1 - G_y(x)) dF_x(x)$$

Under  $H_0$ :

$$\pi = \int_{-\infty}^0 F_x(x) dF_x(x) + \int_0^{\infty} (1 - F_x(x)) dF_x(x)$$

Now, using the conditioning argument on  $X$ , so we can express it like; for example, if I consider  $Y_j < X_i < 0$ . So, this we can consider as the conditioning on  $X_i$ ,  $Y_j < x$  \*the distribution of  $x$  but  $x$  is up to 0 only. So, it will be from  $-\infty$  to 0, but this can be written as simply  $G_{yx} dF_x$ . Similarly, if I consider probability of  $0 < X_i < Y_j$ , then this is = 0 to infinity probability of  $Y_j > X$   $dF_x$ . Then, this becomes 1- ( $G_y(x)$ ) (04:43) of  $Y$ , okay.

So, what we do let us consider under  $H_0$ . So, under  $H_0$   $\pi$  will become  $-\infty$  to 0. So, this term plus this term, I have written the expressions here  $F_x dF_x + 0$  to infinity  $1 - F_x dF_x$ .

**(Refer Slide Time: 05:30)**

© CET  
I.I.T. KGP

So put  $F_X(x) = u$ .

$$\pi = \int_0^{1/2} u \, du + \int_{1/2}^1 (1-u) \, du = \frac{1}{8} + \frac{1}{8} = \frac{1}{4}$$

$$E(T) = E\left(\sum \sum D_{ij}\right) = mn \pi$$

$$E_0(T) = \frac{mn}{4}$$

$$V(T) = \sum_i \sum_j \sum_{i'} \sum_{j'} \text{cov}(D_{ij}, D_{i'j'})$$

$$= \sum_i \sum_{i'} \sum_j \sum_{j'} \left( E(D_{ij} D_{i'j'}) - \pi^2 \right)$$

So, let us put say  $F_X = U$ . Then,  $\pi =$  at  $-\infty$  this is 0, at 0 this will become 1/2. So, this is becoming  $u \, du$  from 0 to 1/2. Well actually second one will become 1/2 to 1 and this is  $1-u \, du$ . So, both are actually  $1/8 + 1/8 = 1/4$ . So, under the null hypothesis, the probability that  $D_{ij} = 1$  is actually becoming  $= 1/4$ . So, if I consider the expectation of  $T$  under the null hypothesis; of course this is equal to double summation  $D_{ij}$ , so that is  $= mn \pi$ , but under the null hypothesis, this is simply becoming  $mn/4$ .

So, you can see that actually the symmetry will come around this value. Let us look at similarly the variance term here. So, variance  $T$  is  $=$ , we can write the general term covariance  $D_{ij} D_{i'j'}$  where the sum is over all  $i$ 's and  $j$ 's here. So, this is then  $=$  expectation of  $D_{ij} D_{i'j'}$  minus  $\pi^2$ . So, this will be one only when  $D_{ij}$  and  $D_{i'j'}$  both are one. In all other cases, this will be  $= 0$ . So, this is simply equal to the probability of  $D_{ij} = 1$  and  $D_{i'j'} = 1$ .

**(Refer Slide Time: 08:03)**

$$\begin{aligned}
&= \sum_i \sum_j \sum_{i'} \sum_{j'} \{P(D_{ij}=1, D_{i'j'}=1) - \pi^2\} \\
&= \sum_{i=i'} \sum_{j=j'} \{P(D_{ij}=1) - \pi^2\} + \sum_{i=i', j \neq j'} \{P(D_{ij}=1, D_{i'j'}=1) - \pi^2\} \\
&\quad + \sum_{i \neq i'} \sum_{j=j'} \{P(D_{ij}=1, D_{i'j'}=1) - \pi^2\} \\
&\quad + \sum_i \sum_{i'} \sum_{j \neq j'} \sum_{j'} \{P(D_{ij}=1, D_{i'j'}=1) - \pi^2\} \\
&\qquad \qquad \qquad \downarrow P(D_{ij}=1) \quad P(D_{i'j'}=1) \rightarrow \pi^2 - \pi^2 = 0
\end{aligned}$$

So, we can express it as double summation, quarterpole summation probability of  $D_{ij}=1$ ,  $D_{i'j'}$  prime  $j$  prime  $= 1 - \pi^2$  square. Another thing that we observe since this  $D_{ij}$  is based on  $X_i$  and  $Y_j$ , therefore  $D_{i'j'}$  will be based on  $X_{i'}$  and  $Y_{j'}$ . Since, the random samples are taken, therefore these will be totally independent. So, this can be written separately here. So, let me express it in a full form here.

There will be all cases;  $i$  can be  $= i$  prime,  $j$  can be  $= j$  prime and so on. So, let us consider all the cases here. So, one case is when  $i=i$  prime,  $j=j$  prime, then this will become simply double summation. So, this term then can be written as if  $i=i$  prime,  $j=j$  prime, then this term will become probability of  $D_{ij}=1 - \pi^2$  square. Now, let us consider other case > One case will be when  $i=i$  prime,  $j \neq j$  prime, so in that case this will become triple summation, that is  $i j j$  prime. So, this is then = probability of  $D_{ij}=1, D_{i'j'}$  prime  $= 1 - \pi^2$  square.

Now, this we have to calculate separately, so let me give a notation for this. This will become  $\pi_1$ . So, this is again  $\pi_1$  here, this is  $\pi_1$ . Then, there will be another case. The other case will be when  $i \neq i$  prime but  $j=j$  prime. So, this is  $i i$  prime  $j$ . So, this is probability of  $D_{ij}=1$ , probability of  $D_{i'j'}$  prime  $j=1 - \pi^2$  square. This one let us name it as  $\pi_2$  and then there will be choice when all of them are different, i.e.,  $i i$  prime  $j j$  prime, here  $i \neq i$  prime,  $j \neq j$  prime.

This is probability  $D_{ij}=1, D_{i'j'}$  prime  $j$  prime  $= 1 - \pi^2$  square. In this case, this is actually =  $D_{ij}=1, D_{i'j'}$

prime  $j$  prime=1, why because  $X_i$   $X_i$  prime  $Y_j$   $Y_j$  prime they are all independent. So,  $D_{ij}$  will become independent of  $D_{ij}$  prime  $D_i$  prime  $j$  prime. So, then this is nothing but  $\pi_i$  square, so  $\pi_i$  square- $\pi_i$  square, that is it becoming = 0. So, this term vanishes. We are left with the this, this and this term.

(Refer Slide Time: 11:53)

$$= mn(\pi - \pi^2) + mn(n-1)(\pi_1 - \pi^2) + mn(m-1)(\pi_2 - \pi^2)$$

$$\pi_1 = P(D_{ij} = 1, D_{ij'} = 1, j \neq j')$$

$$= P(\{Y_j < X_i < 0 \text{ or } 0 < X_i < Y_j\} \cap \{Y_{j'} < X_i < 0 \text{ or } 0 < X_i < Y_{j'}\})$$

$$= \int_{-\infty}^{\infty} P(\{Y_j < x < 0 \text{ or } 0 < x < Y_j\} \cap \{Y_{j'} < x < 0 \text{ or } 0 < x < Y_{j'}\}) dF_X(x)$$

$$= \int_{-\infty}^{\infty} [P(Y_j < x < 0) + P(0 < x < Y_j)] [P(Y_{j'} < x < 0) + P(0 < x < Y_{j'})] dF_X(x)$$

So, in terms of the notations  $\pi_i$ ,  $\pi_i$  square  $\pi_{i1}$ ,  $\pi_{i2}$ , etc. we can express it as, so then this we write as  $mn \pi_i - \pi_i$  square +  $mn * n - 1 \pi_{i1} - \pi_i$  square +  $mn * m - 1 \pi_{i2} - \pi_i$  square. Let us look at the counting of these terms. Here we are taking over all  $i, j$ . So, there will be  $mn$  terms. In the second one, here I am taking  $i = i$  prime but  $j \neq j$  prime. So, these are  $n * n - 1$  and  $i$ 's are  $m$ , so  $m * n * n - 1 \pi_{i1} - \pi_i$  square. Then, in the third one  $j = j$  prime, so that is  $n$  terms and then  $i \neq i$  prime, that is  $m * n - 1$  term.

So, it becomes  $mn * m - 1 \pi_{i2} - \pi_i$  square and the last one which is actually  $m * n - 1 n * m - 1$  but actually this is becoming 0 because this is  $\pi_i$  square- $\pi_i$  square. So, we are left with this much only. Now, let us consider the expressions for these quantities under general and null hypothesis. So,  $\pi_{i1}$  let us look at for example, so that is equal  $D_{ij}=1, D_{ij}$  prime=1 where  $j \neq j$  prime. So, that is = probability of  $Y_j < X_i < 0$  or  $0 < X_i < Y_j$ , that is  $D_{ij}=1$  and we will be taking intersection with the event  $Y_j$  prime  $< X_i < 0$  or  $0 < X_i < Y_j$  prime.

So, here you can notice here  $X_i$  is fixed here, so we can do the conditioning on that. So, this

becomes probability of  $Y_j < X < 0$  or  $0 < X < Y_j$  intersection  $Y_j \text{ prime} < X < 0$  or  $0 < X < Y_j \text{ prime}$   $dF_x$ . So, that is =  $Y_j$  and  $Y_j \text{ prime}$  are independent. Therefore, these 2 probabilities can be written as a product here,  $Y_j < X < 0$  or  $0 < X < Y_j$ . In fact, you can write it as sum here into probability of  $Y_j \text{ prime} < X < 0$  + probability of  $0 < X < Y_j \text{ prime}$   $df_x$ . Since,  $Y_j$  and  $Y_j \text{ prime}$  have the same distribution, therefore this quantity will be same as this.

(Refer Slide Time: 16:00)

$$\begin{aligned}
 &= P(\{Y_j < X < 0 \text{ or } 0 < X < Y_j\} \cap \{Y_j \text{ prime} < X < 0 \text{ or } 0 < X < Y_j \text{ prime}\}) \\
 &= \int_{-\infty}^{\infty} P(\{Y_j < x < 0 \text{ or } 0 < x < Y_j\} \cap \{Y_j \text{ prime} < x < 0 \text{ or } 0 < x < Y_j \text{ prime}\}) dF_x(x) \\
 &= \int_{-\infty}^{\infty} [P(Y_j < x < 0) + P(0 < x < Y_j)] [P(Y_j \text{ prime} < x < 0) + P(0 < x < Y_j \text{ prime})] dF_x(x) \\
 &= \int_{-\infty}^{\infty} [P(Y_j < x < 0) + P(0 < x < Y_j)]^2 dF_x(x)
 \end{aligned}$$

So, we can write it as the square term here.

(Refer Slide Time: 16:04)

$$\begin{aligned}
 &= \int_{-\infty}^{\infty} \{P(Y_j < x < 0)\}^2 dF_x(x) + \int_{-\infty}^{\infty} \{P(0 < x < Y_j)\}^2 dF_x(x) \\
 &\quad + 2 \int_{-\infty}^{\infty} P(Y_j < x < 0) P(0 < x < Y_j) dF_x(x) \\
 &\quad \quad \quad \text{disjoint sets} \rightarrow 0 \\
 &= \int_{-\infty}^0 [G_y(x)]^2 dF_x(x) + \int_0^{\infty} [1 - G_y(x)]^2 dF_x(x) \\
 \text{Under } H_0: \\
 \pi_1 &= \int_{-\infty}^0 \{F_x(x)\}^2 dF_x(x) + \int_0^{\infty} \{1 - F_x(x)\}^2 dF_x(x)
 \end{aligned}$$

So, that is = probability of  $Y_j < X < 0$  square  $df_x$  - infinity to infinity probability of  $0 < X < Y_j$  square  $df_x$  + twice - infinity to infinity probability of  $Y_j < X < 0$  \* probability  $0 < X < Y_j$   $df_x$ . Now, you look at

this one. See, this is saying  $Y_j < X <$  and of course  $X < 0$ . This is  $Y_j > X$ . Now, under the same distribution of  $f$ , that means same distribution of  $X$  we are having 2 disjoint sets here. So, these 2 are disjoint sets. If these are 2 disjoint sets, so therefore this would be  $= 0$ .

Because these 2 events cannot occur together, like if I have to put integral, then for this one it is  $-\infty$  to 0, for this one it has to be 0 to infinity. So, both of them cannot occur simultaneously. So, this term will become simply  $= 0$ . So, this one now it is  $= -\infty$  to 0. This is the CDF of  $Y$  square  $\cdot df_x$  and the second one is then 0 to infinity  $1 - \text{CDF}$  of  $X$   $df_x$ . So, this is the general expression now we have obtained for  $\pi_1$ . Now, under the special case when  $F$  and  $G$  are same, then this become  $= -\infty$  to 0  $F_x$  square  $df_x + 0$  to infinity  $1 - F_x$  square  $df_x$ .

**(Refer Slide Time: 18:34)**

$$\begin{aligned}
 & + 2 \int_{-\infty}^0 P(Y_j < X < 0) P(0 < X < Y_j) df_x(x) \\
 & \quad \text{disjoint sets} \rightarrow 0 \\
 & = \int_{-\infty}^0 [G_y(x)]^2 df_x(x) + \int_0^{\infty} [1 - G_y(x)]^2 df_x(x) \\
 & \text{Under } H_0: \\
 \pi_1 & = \int_{-\infty}^0 \{F_x(x)\}^2 df_x(x) + \int_0^{\infty} \{1 - F_x(x)\}^2 df_x(x) \\
 & = \int_0^{1/2} u^2 du + \int_{1/2}^1 u^2 du = 1
 \end{aligned}$$

So, when you put  $F_x = u$ , then this can be written as say 0 to  $1/2$   $u$  square  $du + 0$  to  $1/2$ ,  $1 - F_x$  you can put here. So,  $u$  square  $du$ . So, this is then becoming  $= 1/12$ . This will become  $1/3$  here, so  $u$  cube/3. So, when you put 2 here  $1/24 + 1/24$  is  $= 1$ . In a similar way, if you look at the expression for  $\pi_2$ . In  $\pi_2$ , what is happening, the roles of  $X_i$ 's and  $Y_j$ 's you can interchange. So, I will not write the expression for that now in full detail.

**(Refer Slide Time: 19:32)**

$\pi_2$  can be obtained from  $\pi_1$  by interchanging the role of X's & Y's.

Hence  $H_0$ ,  $\pi_2 = \frac{1}{12}$ .

So

$$\begin{aligned}
 V_0(T) &= mn \cdot \frac{1}{4} \cdot \frac{3}{4} + mn(n-1) \left( \frac{1}{12} - \frac{1}{16} \right) \\
 &\quad + nm(m-1) \left( \frac{1}{12} - \frac{1}{16} \right). \\
 &= \frac{mn(m+n+7)}{48}.
 \end{aligned}$$

$\pi_2$  can be obtained from  $\pi_1$  by interchanging the role of X's and Y's. So, under  $H_0$ ,  $\pi_2$  will then become  $= 1/12$ . So, variance of T under  $H_0$ , that is a  $mn \cdot 1/4 \cdot 3/4$ , that is  $\pi_i - \pi_i^2 + mn \cdot n - 1 \cdot 1/12 - 1/16 + nm \cdot m - 1 \cdot 1/12 - 1/16$ . Of course, you can simplify this. It becomes  $mn \cdot m + n + 7/48$ . So, the null distribution for Sukhatme test statistic has been obtained here. The expectation T is  $mn/4$  and the variance of T under the null hypothesis is obtained.

So, this Sukhatme test statistic can also be used for testing the 2 sample scale problem. As I mentioned here that the small t indicates that  $\theta > 1$ , a large T will indicate  $\theta < 1$ . So, this can be used and also we have obtained the null distribution of that. As I mentioned now, I am discussing the large sample property of the tests for the nonparametric situations.

**(Refer Slide Time: 21:33)**

C O C E T  
I I T K G P 8

Consistency of Statistical Tests

Let  $T_n$  be a level  $\alpha$  test statistic based on  $n$  observations  
for testing  $H_0: G \in \Omega_{\text{null}}$  vs  $H_1: G \in \Omega_{\text{alt}}$   
 $= \Omega - \Omega_{\text{null}}$  (U)

Then the test based on  $T_n$  is consistent if

$$P_{G \in \Omega_{\text{alt}}}(\text{Rej } H_0) \rightarrow 1 \text{ as } n \rightarrow \infty$$

Example:  $X_1, X_2, \dots \sim N(\theta, 1)$ .

$H_0: \theta = 0$ vs $H_1: \theta > 0$	}	Consider the UMP test Reject $H_0$ if $\sqrt{n} \bar{X}_n > Z_{\alpha}$ .
---	---	--

NPTEL

So, this property is called the consistency of statistical tests. So, you can actually think of the consistency property of the estimator. In the point estimation, how do we define the consistency. We consider the probability that the estimator approaches the true value of the parameter converges to 1. In the case of testing, we can consider the power function. If the function approaches 1, that means the power becomes large and large as the sample size increases, then we can consider it as a consistent test.

So, it is similar to the consistency of the estimator in the sense that here the power will increase here. So, let me define here. Let  $T_n$  be a level  $\alpha$  test statistic based on  $n$  observations. For testing,  $H_0$  say  $G$  belongs to  $\Omega_{\text{null}}$  versus  $H_1$   $G$  belongs to  $\Omega_{\text{alt}}$  which is actually  $= \Omega - \Omega_{\text{null}}$ , okay. This is my testing problem here. Then, the test based on  $T_n$  is consistent if probability say  $G$  belongs to  $\Omega_{\text{alt}}$  rejecting  $H_0$ . This goes to 1 as  $n$  tends to infinity.

So, it is same the power of the test going to 1. Let me consider a simple application of this. Let us consider say observations from a normal distribution with mean  $\theta$  and variance unity and we are considering the standard test for the hypothesis testing problem,  $\theta=0$  against  $\theta>0$ . So, consider the most powerful, that is we call it UMP test here, uniformly most powerful test that is reject  $H_0$  if the root  $n \bar{X}_n > Z_{\alpha}$ , that is a level  $\alpha$  test here.

**(Refer Slide Time: 24:47)**

© CEE  
I.I.T. KGP

Let  $\theta_1 > 0$ .

$$P_{\theta_1}(\sqrt{n}\bar{X} > z_\alpha) = P_{\theta_1}(\sqrt{n}(\bar{X} - \theta_1) > z_\alpha - \sqrt{n}\theta_1)$$

$$= P(Z > z_\alpha - \sqrt{n}\theta_1)$$

$$\rightarrow 1 \text{ as } n \rightarrow \infty.$$

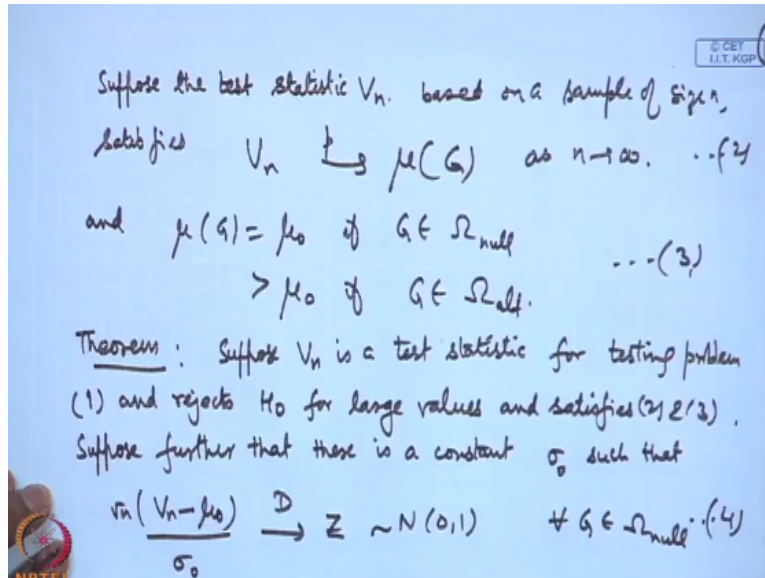

So  $\sqrt{n}\bar{X}_n$  is a consistent test statistic  
and  $(\sqrt{n}\bar{X}_n > z_\alpha)$  is consistent test region

Remark: In nonparametric situations this type of testing is difficult since we don't have any knowledge of the distribution of  $X$ 's, except that it is continuous.

So, we consider at a point  $\theta_1$ . So, let us take say  $\theta_1 > 0$ , what is the power at this point,  $\sqrt{n}\bar{X} > z_\alpha$ , that is = probability of  $\sqrt{n}\bar{X} - \theta_1 > z_\alpha - \sqrt{n}\theta_1$ . When  $\theta_1 = \theta_1$ , this will have the standard normal distribution. So, this is probability of  $Z > z_\alpha - \sqrt{n}\theta_1$ . Now, as  $n$  tends to infinity what happens here, here  $\theta_1$  is positive, therefore this value will go to  $-\infty$ .

So,  $Z > -\infty$  this will go to 1 as  $n$  tends to infinity. So,  $\sqrt{n}\bar{X}_n$  is a consistent test statistic and this test is actually consistent that is  $\sqrt{n}\bar{X}_n > z_\alpha$ , this is consistent test region, that is consistent critical region here, okay. In the nonparametric situation, directly specifying this kind of thing is difficult here, because we do not have the knowledge of the probability distribution here. So, we cannot write down this kind of statement. So, we define in a different way. In nonparametric situations, this type of testing is difficult since we do not have any knowledge of the distribution of  $X$ 's, except that it is continuous.

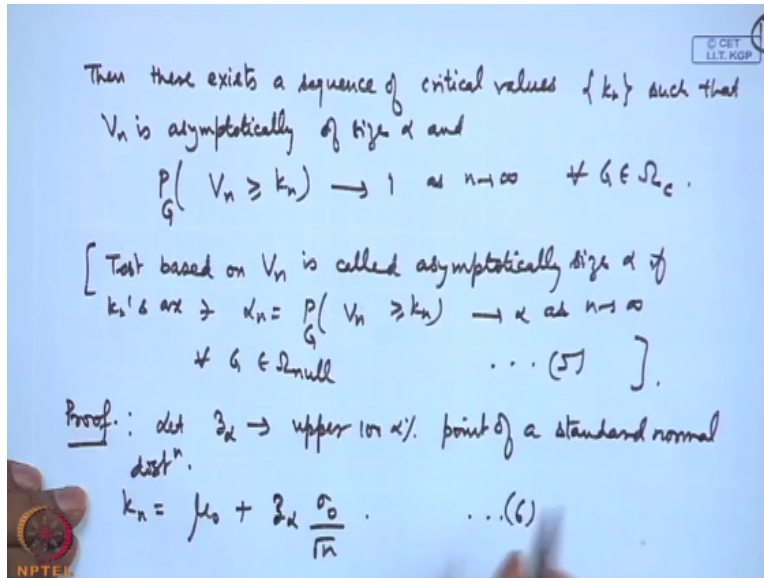

**(Refer Slide Time: 27:30)**

Let us consider suppose the test is statistic  $V_n$  based on a sample of size  $n$  satisfies  $V_n$  converges to  $\mu$  of  $G$  in probability as  $n$  tends to infinity and the function  $\mu$  satisfies  $\mu(G) = \mu_0$  if  $G$  belongs to  $\Omega_{null}$  and it is  $> \mu_0$  if  $G$  belongs to  $\Omega_{alt}$ . Let me give this numbering here. So, we have the following result then regarding the consistency here. Suppose  $V_n$  is a test statistic for the situation 1, 1 is the hypothesis testing problem,  $G$  belongs to  $\Omega_{null}$  against  $H_1$ ,  $G$  belongs to  $\Omega_{alt}$ .

So, suppose  $V_n$  is a test statistic for testing problem 1 and rejects  $H_0$  for large values and satisfies 2 and 3, that means it is consistent that is convergence and probability to  $\mu(G)$  function and this  $\mu(G)$  itself satisfies that under the null hypothesis, it is equal to some fixed value  $\mu_0$  and under the alternative hypothesis it is  $> \mu_0$ . So, basically we are trying to put it in the framework of a parametric testing problem here. Suppose further that there is a constant  $\sigma_0$  such that  $\sqrt{n}(V_n - \mu_0)/\sigma_0$  converges in distribution to standard normal distribution for all that is under the null hypothesis.

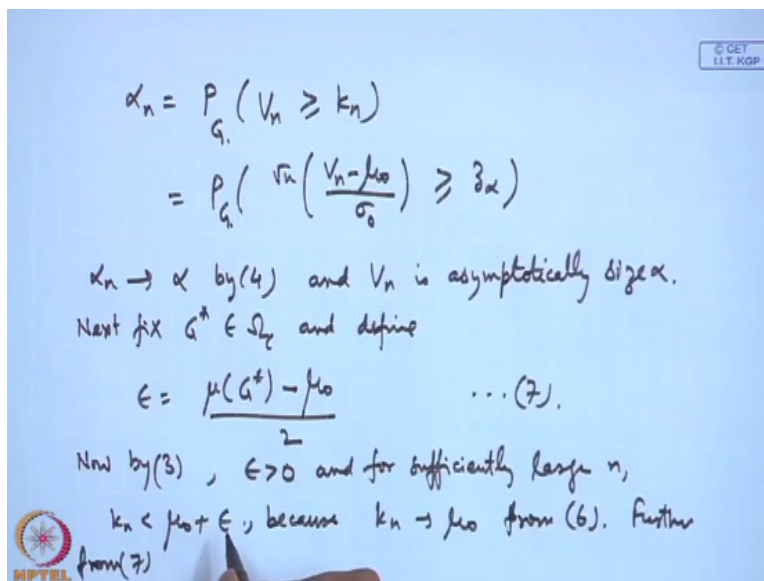

**(Refer Slide Time: 30:32)**

Then, there exists a sequence of critical values  $K_n$  such that  $V_n$  is asymptotically of size  $\alpha$  and probability of  $V_n \geq K_n$  under  $G$  is going to 1 as  $n$  tends to infinity for all  $G$  in the alternative, okay. Asymptotically size  $\alpha$  let me define here, test based on  $V_n$  is called asymptotically size  $\alpha$  if  $K_n$ 's are such that  $\alpha_n = \text{probability } V_n \geq K_n$  goes to  $\alpha$  as  $n$  tends to infinity for all  $G$  belonging to  $\omega$  null.

Let me prove this. So, let  $Z_\alpha$  with the upper hundred  $\alpha$  percent point of the standard normal distribution. So, let us define say  $K_n = \mu_0 + Z_\alpha \sigma_0 / \sqrt{n}$ .

**(Refer Slide Time: 32:55)**

So, let us consider say  $\alpha_n = \text{probability of } V_n \geq K_n$ , so that is = probability of  $\sqrt{n} V_n -$

$\mu_0/\sigma_0 \geq Z_{\alpha}$ . So,  $\alpha/n$  goes to  $\alpha/4$ , we have assumed here the asymptotic normality here and  $V_n$  is asymptotically size  $\alpha$ . Now, we fix here  $G^*$  belonging to  $\omega_C$  and define  $\epsilon = \mu(G^*) - \mu_0/2$ . So, by 3,  $\epsilon$  will be  $> 0$  and for sufficiently large  $n$ ,  $K_n < \mu_0 + \epsilon$  since  $K_n$  goes to  $\mu_0$  from 6.

**(Refer Slide Time: 34:46)**

$\mu_0 = \mu(G^*) - 2\epsilon$   
 Hence  $K_n < \mu(G^*) - \epsilon \quad \dots (8)$   
 Now  $|V_n - \mu(G^*)| < \epsilon \Rightarrow V_n - \mu(G^*) > -\epsilon$   
 $\Rightarrow V_n > \mu(G^*) - \epsilon \Rightarrow V_n \geq K_n \quad (\text{from } (8))$   
 Hence  
 $P(|V_n - \mu(G^*)| < \epsilon) \leq P_{G^*}(V_n \geq K_n) \leq 1.$   
 By 2, the LHS  $\rightarrow 1$ , hence  $P_{G^*}(V_n \geq K_n) \rightarrow 1.$   
 Since  $G^*$  was arbitrarily fixed in  $\omega_C$ , the theorem is proved.

From 7, we will have  $\mu_0 = \mu(G^*) - 2\epsilon$ , hence  $K_n < \mu(G^*) - \epsilon$ . So, if we consider now modulus of  $V_n - \mu(G^*) < \epsilon$ , this will imply that  $V_n - \mu(G^*) > -\epsilon$  which implies that  $V_n > \mu(G^*) - \epsilon$  which implies that  $V_n \geq K_n$  from 8 because of this condition here. So, this implies that probability of modulus  $V_n - \mu(G^*) < \epsilon$  for the distribution  $G^*$ , it is  $\leq$  probability of  $V_n \geq K_n$  under the distribution  $G^*$  that is  $\leq 1$ .

Now by the equation number 2 that we have taken here, that is  $V_n$  goes to  $\mu(G)$  as  $n$  tends to infinitely, so therefore the left-hand side converges to 1, hence probability of  $V_n \geq K_n$  goes to 1. Since  $G^*$  was arbitrarily fixed in  $\omega_C$ , the theorem is proved. We will prove the consistency of some standard test here.

Consistency of the Sign Test

$K \rightarrow$  Sign Test statistic

$$\bar{K} = \frac{K}{N}$$

$$P(|\bar{K} - (1 - F(-\theta))| > \epsilon) \leq \frac{(1 - F(-\theta))(F(-\theta))}{N}$$

$\rightarrow 0$  as  $N \rightarrow \infty$ .

Hence  $\bar{K} \xrightarrow{P} (1 - F(-\theta)) = \mu(F, \theta)$ .

Hence  $\mu(F, \theta) = \frac{1}{2}, \theta = 0, \forall F \in \Omega_0$   
 $> \frac{1}{2}, \theta > 0, \forall F \in \Omega_1$ .

NPTEL

Let us consider say consistency of the sign test here. The sign test that we had introduced firstly for testing whether the median is  $= 0$  or  $> 0$  or  $< 0$ . So, let us consider here  $K$  is the sign test statistic. So, let us define say  $\bar{K} = K/N$ , so probability of  $\bar{K} - 1 - F$  of  $-\theta > \epsilon$ . This is  $\leq$  by (i) (37:53) in equality  $1 - F$  of  $-\theta * F$  of  $-\theta/N$  and this goes to 0 as  $N$  tends to infinity. So,  $\bar{K}$  converges to  $1 - F - \theta$  in probability, that is  $\mu$  of  $F, \theta$ .  $\mu$  of  $F, \theta = 1/2$  and it is  $> 1/2$  for  $\theta > 0$ .

**(Refer Slide Time: 38:42)**

I.I.T. KGP

and the sign test separates the null hyp.  $F \in \Omega_0, \theta = 0$   
 from the alternative  $F \in \Omega_1, \theta > 0$ .

The consistency set for the sign test is the class of absolutely continuous dist<sup>ns</sup>. with unique positive median.

The required asymptotic normality follows from the fact that  $\frac{K - E(K)}{\sqrt{\text{var}(K)}}$  has asymptotic standard normal dist<sup>n</sup>. with  $\mu_0 = \frac{1}{2}$  &  $\sigma_0 = \frac{1}{2}$ .

Remark: Certainly consistency is a desirable property for any test and so a test which is not consistent must be outright rejected.

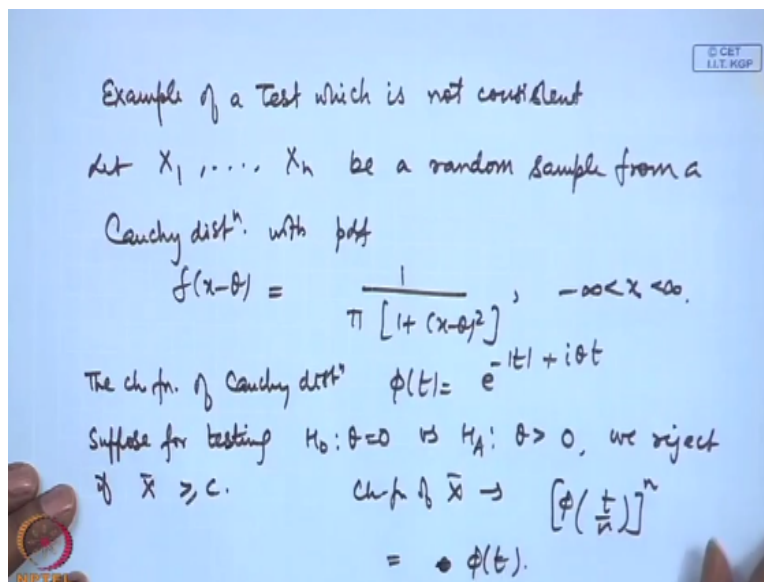

NPTEL

The sign test separates the null hypothesis  $F$  belonging to  $\Omega_0, \theta = 0$  from the alternative  $F$  belonging to  $\Omega_1, \theta > 0$ . The consistency set for the sign test is the class of absolutely continuous distributions with unique positive median. The required asymptotic normality will

follow from the fact that  $K$ -expectation  $K/\text{square root of variance } K$  has asymptotic standard normal distribution with  $\mu_0=1/2$  and  $\sigma_0=1/2$ .

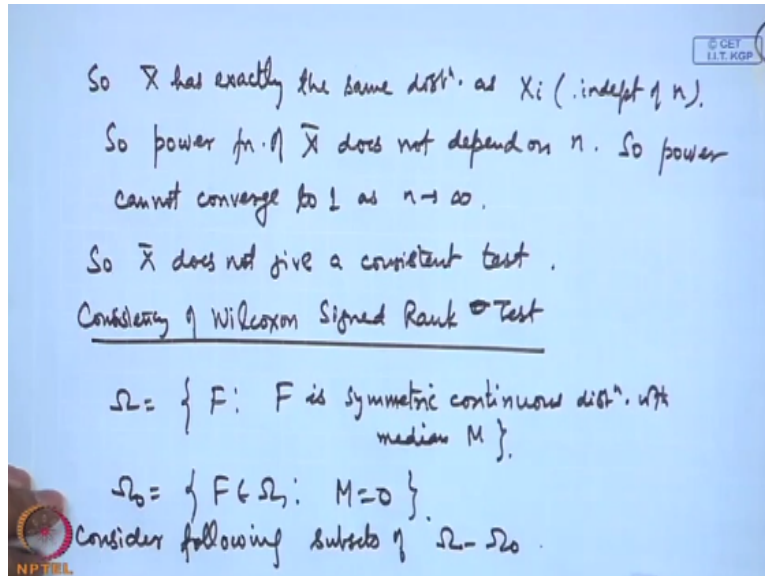

Any reasonable test should be actually consistent, therefore actually consistency does not provide a criteria for distinguishing among tests; however, if a test is not consistent, then certainly it is a defective test. So, that means basically all the go test must be consistent test. So, let me just give it as a remark here. Certainly, consistency is a desirable property for any test; and so, a test which is not consistent must be outright rejected.

**(Refer Slide Time: 41:52)**

Let me consider a test which is not consistent. So, let us consider say  $X_1, X_2, \dots, X_n$  be a random sample from a Cauchy distribution, that is with pdf suppose I am considering the location form  $1/\pi 1+x$ -theta square. Actually, we know the characteristic function. The characteristic function of Cauchy distribution, that is  $\phi(t) = e^{-|t| + i\theta t}$ . So, suppose for testing  $H_0, \theta = 0$  against alternative  $\theta > 0$ , we reject if  $\bar{X}$  is  $\geq c$ . So, if we consider this characteristic function of  $\bar{X}$ , then it is same as  $\phi$  of  $t/n$  to the power  $n$  that is equal to same thing basically, because of this form it will turn out to be  $\phi(t)$  itself.

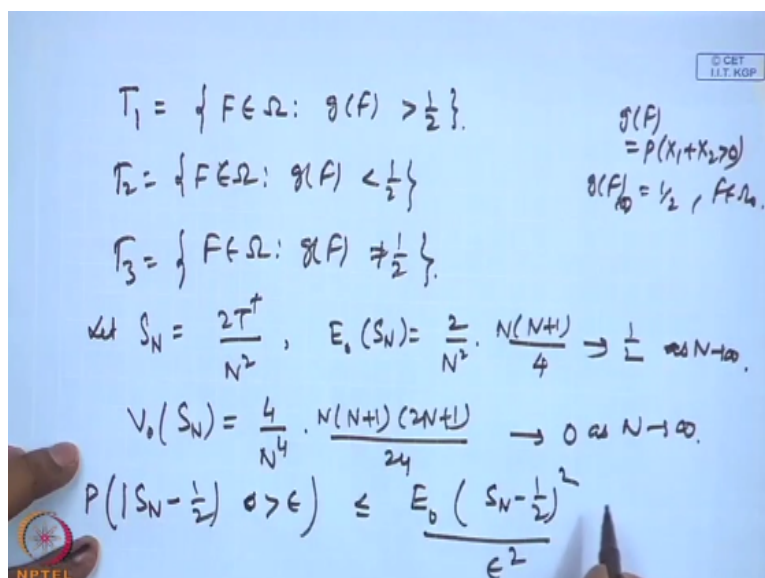

**(Refer Slide Time: 43:53)**

So what we are concluding here is that  $\bar{X}$  has exactly the same distribution as  $X_i$ , that is it is independent of  $n$ . So, power function of  $\bar{X}$  does not depend upon  $n$ . So, power cannot converge to 1 as  $n$  tends to infinity. So,  $\bar{X}$  does not give a consistent test. So, this is an example of a bad test. I have proved the consistency of the sign test. Let us also consider the consistency of the Wilcoxon test.

So,  $\Omega$  is the class of symmetric continuous distribution with median given by  $m$  and  $\Omega_0$  is the class where we say that median=0. So, we consider the following subsets for alternatives, following subsets of  $\Omega - \Omega_0$ . So, these are for defining the alternative hypothesis here.

**(Refer Slide Time: 46:05)**

Let me call it gamma one, that is F belongs to omega where  $Gf > 1/2$ . So, basically here  $Gf$  is probability of  $X_1 + X_2 > 0$ . Under null hypothesis, this is  $= 1/2$ . Omega 2 is where  $Gf < 1/2$  and gamma 3 f belonging to omega where  $Gf \neq 1/2$ . Let us consider here  $S_n$ , that is  $2T^+ / \text{Normal square}$ . So, if I consider expectation of  $S_n$  that is  $= 2/N \text{ square} * N * N + 1/4$ . Naturally, this will converge to  $1/2$  as  $N$  tends to infinity.

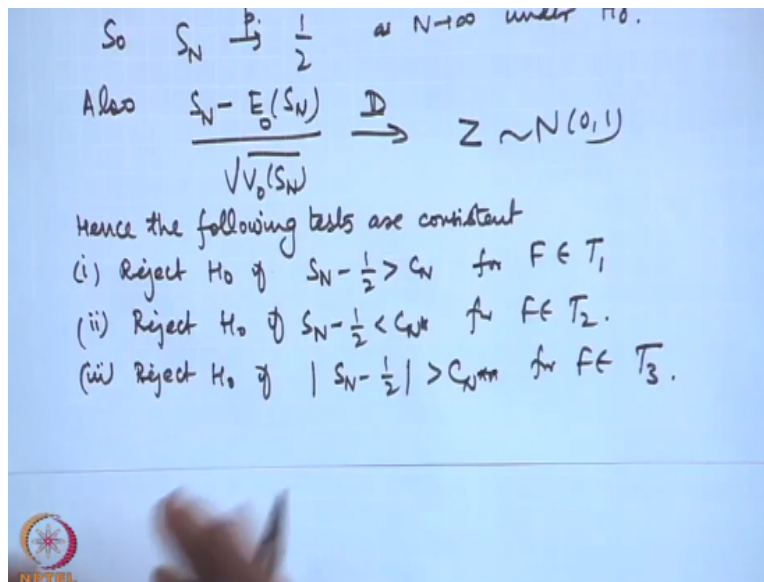

Similarly, if I consider variance of  $S_n$ , then that is  $4/n$  to the power 4 variance of  $T^+$  that is  $N * N + 1 * 2N + 1/24$  that goes to 0 as  $N$  tends to infinity, this goes to  $1/2$ . So, if I consider probability of  $S_n - 1/2$  modulus being  $> \epsilon$ , then by (i) (47:43) inequality it is  $\leq$  expectation of  $S_n - 1/2$  square /  $\epsilon^2$  and this we simply split into 2 parts.

**(Refer Slide Time: 47:53)**

$$= \frac{1}{\epsilon^2} \left[ V_0(S_N) + \left(\frac{1}{2N}\right)^2 \right] \rightarrow 0 \text{ as } N \rightarrow \infty.$$
 So  $S_N \xrightarrow{p} \frac{1}{2}$  as  $N \rightarrow \infty$  under  $H_0$ .  
 Also  $\frac{S_N - E_0(S_N)}{\sqrt{V_0(S_N)}} \xrightarrow{D} Z \sim N(0,1)$   
 Hence the following tests are consistent  
 (i) Reject  $H_0$  if  $S_N - \frac{1}{2} > C_n$  for  $F \in T_1$   
 (ii) Reject  $H_0$  if  $S_N - \frac{1}{2} < -C_n$  for  $F \in T_2$ .

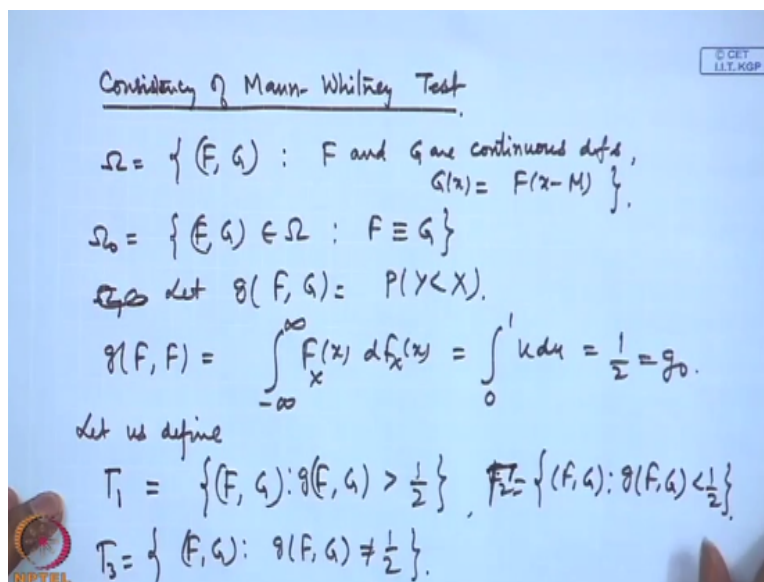

That is  $= 1/\epsilon^2$  variance of  $S_n - 1/2$  whole square. So, this goes to 0 as  $N$  tends to infinity. So, what we have proved here that  $S_n$  converges to  $1/2$  in probability as  $N$  tends to infinity under  $H_0$  and the asymptotic distribution of  $S_n$  is also normal, hence the following tests will be consistent, that is reject  $H_0$  if  $S_n - 1/2 > C_n$  for  $F$  belonging to gamma 1, reject  $H_0$  if  $S_n - 1/2 < -C_n$  for  $F$  belonging to gamma 2.

**(Refer Slide Time: 49:15)**

Thirdly reject  $H_0$  if modulus of  $S_n - 1/2 > say C_n$  double star for  $F$  belonging to  $\gamma_3$ . All of these 3 tests statistics will be consistent.

(Refer Slide Time: 49:40)

Since, this Mann-Whitney test was simply a variation here from the Wilcoxon, let us prove the consistency of Mann-Whitney also. I would just like to explain once again here the consistency of the Wilcoxon signed rank statistic. In the null hypothesis, we are saying the median is 0. So, here we are saying on either side that the median is  $> 0$ ,  $< 0$  or  $\neq 0$ .

So, to prove this what we considered is that consistency under asymptotic normality, then for the one-sided alternative, that is  $\theta > 0$  when we are having the right-hand side as the rejection

region, then this is a consistent test. For  $m < 0$  when we have the alternative, the left hand rejection region is consistent and the 2-sided rejection region will be consistent when we have the 2-sided alternative hypothesis here.

Now, let us consider consistency of Mann-Whitney test statistic. So, we define  $\omega$  = the class of all 2 sample problems. So,  $F$  and  $G$  are continuous distribution functions and  $G \neq F$  of  $X \sim M$ . So,  $\omega_0$  is the case when  $M=0$  that means we are considering  $F, G$  belonging to  $\omega$  such that  $F$  and  $G$  are the same. Let us define  $G$  of  $F, G$  that is = probability of  $Y < X$ . So,  $G$  of  $F, F$  that is =  $\int_0^1 F(x) dx$  that is =  $\int_0^1 u du = 1/2$  that we call it is =  $G_0$ . So, we define the alternative hypothesis sets as  $F, G$  such that  $G$  of  $F, G$  is  $> 1/2, < 1/2, \gamma_2$  or  $\gamma_3$ .

**(Refer Slide Time: 52:51)**

$$\text{Let } S_{m,n} = \frac{U_{m,n}}{mn}, \quad E_0(S_{m,n}) = \frac{mn}{2} \cdot \frac{1}{mn} = \frac{1}{2} = G_0.$$

$$V_0(S_{m,n}) = \frac{1}{m^2 n^2} \cdot \frac{mn(m+n+1)}{12} \rightarrow 0 \text{ as } \min(m,n) \rightarrow \infty.$$

$$\text{Hence } P(|S_{m,n} - \frac{1}{2}| > \epsilon) \leq \frac{V_0(S_{m,n})}{\epsilon^2} \rightarrow 0$$

$$\text{So } S_{m,n} \xrightarrow{p} \frac{1}{2} \text{ as } \min(m,n) \rightarrow \infty \text{ under } H_0.$$

$$\text{Also } \frac{S_{m,n} - E_0(S_{m,n})}{\sqrt{\text{Var}_0(S_{m,n})}} \xrightarrow{D} Z \sim N(0,1)$$

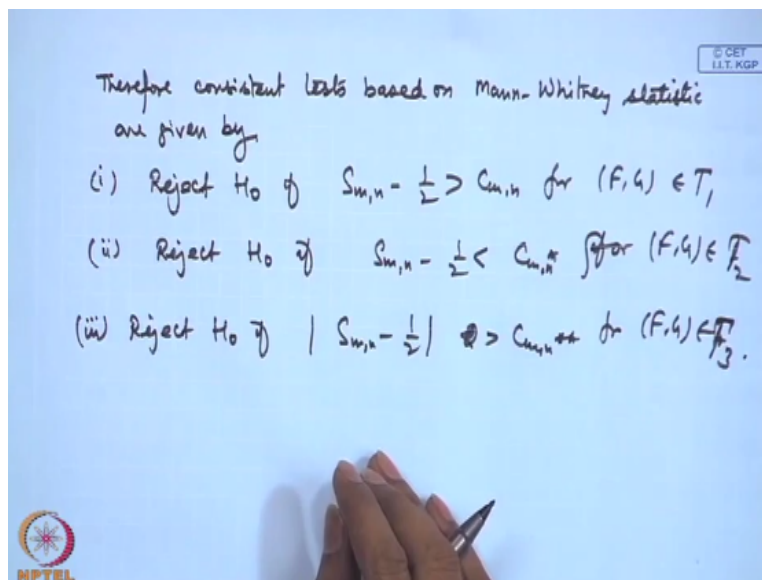

Let us consider here  $S_{mn} = U_{mn}/mn$ , this  $U_{mn}$  was the Mann-Whitney statistics, so we are considering scaling by  $mn$  here. So, expectation of  $S_{mn} = mn/2 * 1/mn = 1/2 = G_0$ . Let us consider variance of  $S_{mn} = 1/m^2 n^2 * mn(m+n+1)/12$ , this goes to 0 as minimum of  $mn$  goes to infinity.

Because one of the  $mn$ 's will cancel out and the term will become  $1/m + 1/n + 1/mn$ , so if minimum of  $mn$  goes to 0, then both of the terms will go to 0 and if I consider then  $S_{mn} - 1/2$  probability of this  $> \epsilon$ , then this is  $\leq$ , well again we can show that this is  $\leq$  variance of  $S_{mn}/\epsilon^2$ , this goes to 0. So, we are concluding that  $S_{mn}$  goes to  $1/2$  in probability as minimum of

mn goes to infinity under  $H_0$ .

Also the asymptotic distribution is established under  $H_0$ , this goes to  $Z$  following normal  $0, 1$ . Since these 2 properties are satisfied, we conclude that the Mann-Whitney test statistics will be consistent provided we define it in the following question. We have the 3 alternative hypothesis, one is when we are considering  $gFG > 1/2$ , so we consider the right-handed rejection region, here we consider the left-handed rejection region, here we consider the 2-sided rejection region here.

**(Refer Slide Time: 55:30)**

So, let me define it here, therefore consistent tests based on Mann-Whitney statistic are given by reject  $H_0$  if  $S_{m,n} - 1/2 > C_{m,n}$  for  $F, G$  belonging to gamma 1, reject  $H_0$  if  $S_{m,n} - 1/2 < C_{m,n}$  for  $F, G$  belonging to gamma 2 and thirdly, reject  $H_0$  if modulus of  $S_{m,n} - 1/2$  is  $> C_{m,n}$  for  $F, G$  belonging to gamma 3. So, all of these test functions are actually consistent tests here.

Here we have considered 2 types of 2 sample problems. In one of the 2 sample problems, we are shifting by a location and in another one we are shifting by a scale. So, we want to know whether the shifting is actually significant or not, that means like if we are shifting by the location then we are saying whether that shifting is in the positive direction or it is in the negative direction.

Similarly, in the scale, we are considering  $> 1$  or  $< 1$ , that means whether we are introducing more variability or we are considering less variability. One may also think of general 2 sample

problem in which we do not talk about the location scale, rather we consider whether the 2 distributions are the same or not. It is something like we consider in the one sample problem that we test whether the given distribution function is of a given form. So, we have for example a chi-square test for goodness of fit.

We also introduced the Kolmogorov Smirnov test for single sample problem. So, in a similar way, if we consider a more general form of the hypothesis for a 2 sample problem, that means we simply say whether the 2 distributions are the same or not, then you can consider it as a goodness of fit problem and we can consider a Kolmogorov Smirnov sample tests for this. So, in the lecture I will be actually discussing about the Kolmogorov Smirnov test and we will discuss the concept of efficiency of the tests also. So, in the next lecture, I will take up this part here.
