**The Value of the Derivative**

So we have seen how Cauchy-Riemann conditions hold whenever the derivative is well defined for a function of a complex variable. You have also seen that the Cauchy-Riemann conditions and some continuity properties; together are also sufficient conditions for a derivative to be meaningful.

But we did not explicitly point out what the value of the derivative of a function would be when it is well defined. So, we will quickly use this lecture to explicitly write down the value of the derivative when it exists ok.

**The value of the derivative.**

i

We have seen that if a function

$$f(z) = u(x, y) + i v(x, y)$$

is differentiable at a point, then the Cauchy-Riemann conditions must hold:

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}$$
$$\frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

If a function is differentiable at a point, the value of the derivative at that point can be written in any of the follow

Slide 2 of 2

So, you have given some function  $f$  of  $z$  at (Refer Time: 01:08) as is customary we write it as  $u$  of  $x, y$  plus  $i$  times  $v$  of  $x, y$ . And if it is differentiable at a point then the Cauchy-Riemann conditions hold:  $\frac{\partial u}{\partial x}$  is equal to  $\frac{\partial v}{\partial y}$  and  $\frac{\partial u}{\partial y}$  is equal to minus  $\frac{\partial v}{\partial x}$ . So, the value of the derivative is also something that can be represented in terms of these partial derivatives right.

(Refer Slide Time: 01:35)

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y}$$
$$\frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

If a function is differentiable at a point, the value of the derivative at that point can be written in any of the following equivalent ways:

$$\begin{aligned}\frac{df(z)}{dz} &= \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \\ &= \frac{\partial v}{\partial y} + i \frac{\partial v}{\partial x} \\ &= \frac{\partial v}{\partial y} - i \frac{\partial u}{\partial y} \\ &= \frac{\partial u}{\partial x} - i \frac{\partial u}{\partial y}\end{aligned}$$

So, any of these following four equivalent ways are acceptable right. So, in fact you know one way in which we argued that you know Cauchy-Riemann conditions well must hold is by trying to work out this derivative in different directions right. So, if you recall from one of the earliest discussions around Cauchy-Riemann conditions. So we in fact, argued that if you have approaching one direction you would get to  $du$  by  $dx$  plus  $i$  times  $dv$  by  $dx$ .

But I mean you can also derive one of these and then simply use the Cauchy-Riemann condition, so you have  $du$  by  $dx$  is equal to  $dv$  by  $dy$ . So, in place of  $du$  by  $dx$  you can put  $dv$  by  $dy$  and leave  $dv$  by  $dx$  as it is, or it may be sometimes more convenient to you know replace both of these.

So, you have  $dv$  by  $dy$  for the real part and you write the imaginary part as minus  $du$  by  $dy$ . Or it may be sometimes convenient to just work out  $du$  by  $dx$  and then the imaginary part to be just minus  $du$  by  $dy$  correct. So, all of these are really the same and they better be right so that is the content of the Cauchy-Riemann conditions.

(Refer Slide Time: 03:04)

On the other hand, if a function is written in polar coordinates as

$$f(z) = u(r, \theta) + i v(r, \theta)$$

is differentiable at a point, then the Cauchy-Riemann conditions that hold there are:

$$\frac{\partial u}{\partial r} = \frac{1}{r} \frac{\partial v}{\partial \theta}$$
$$\frac{\partial v}{\partial r} = -\frac{1}{r} \frac{\partial u}{\partial \theta}$$

Let us now work out the value of the derivative also in polar coordinates.

Using the fact that  $x = r \cos(\theta)$ ,  $y = r \sin(\theta)$ , and the chain rule we have:

$$\frac{\partial u}{\partial r} = \frac{\partial u}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial r}$$
$$= \cos(\theta) \frac{\partial u}{\partial x} + \sin(\theta) \frac{\partial u}{\partial y}$$

Similarly:

So, if a function is differentiable the value of the derivative can be evaluated in any of these above ways also if a function is written in polar coordinates right. So, then also it is convenient to write the real part and imaginary part of your function, but each of these real part and imaginary part must be thought of as functions of  $r$  and  $\theta$  rather than of  $x$  and  $y$  right. So, Cauchy-Riemann conditions we saw where  $\frac{\partial u}{\partial r}$  is equal to  $\frac{1}{r} \frac{\partial v}{\partial \theta}$  of course, we assume that  $r$  is not 0.

So,  $\frac{\partial v}{\partial r}$  is equal to  $-\frac{1}{r} \frac{\partial u}{\partial \theta}$ . Now, the value of the derivative can also be worked out in polar coordinates. So, using the fact that you know  $x$  and  $y$  are defined as  $r \cos \theta$  and  $r \sin \theta$  and using the chain rule. So, we have  $\frac{\partial u}{\partial r}$  is equal to  $\frac{\partial u}{\partial x} \frac{\partial x}{\partial r} + \frac{\partial u}{\partial y} \frac{\partial y}{\partial r}$ .

But  $\frac{\partial u}{\partial x}$  you leave it as it is and  $\frac{\partial x}{\partial r}$  is the same as  $\cos \theta$  and  $\frac{\partial y}{\partial r}$  is  $\sin \theta$ .

(Refer Slide Time: 04:20)

$$\frac{\partial v}{\partial r} = \cos(\theta) \frac{\partial v}{\partial x} + \sin(\theta) \frac{\partial v}{\partial y}.$$

Assuming the Cauchy-Riemann conditions, it is convenient to rewrite the above two equations as:

$$\frac{\partial u}{\partial r} = \cos(\theta) \frac{\partial u}{\partial x} - \sin(\theta) \frac{\partial v}{\partial x}$$

$$\frac{\partial v}{\partial r} = \cos(\theta) \frac{\partial v}{\partial x} + \sin(\theta) \frac{\partial u}{\partial x}.$$

Thus

$$\begin{aligned} \frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} &= \cos(\theta) \frac{\partial u}{\partial x} - \sin(\theta) \frac{\partial v}{\partial x} + i \left[ \cos(\theta) \frac{\partial v}{\partial x} + \sin(\theta) \frac{\partial u}{\partial x} \right] \\ &= [\cos(\theta) + i \sin(\theta)] \frac{\partial u}{\partial x} + i [\cos(\theta) + i \sin(\theta)] \frac{\partial v}{\partial x} \\ &= e^{i\theta} \left[ \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \right]. \end{aligned}$$

In other words:

$$\frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} = e^{-i\theta} \left[ \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \right].$$

So, this  $\frac{\partial u}{\partial r}$  is the same as  $\cos \theta \frac{\partial u}{\partial x} + \sin \theta \frac{\partial u}{\partial y}$ . So, similarly if you took this other function  $\frac{\partial v}{\partial r}$  you know take the function  $v$  of  $r$ ,  $\theta$  and find the partial derivative with respect to  $r$ . So, again you will get the same kind of a relation  $\cos \theta \frac{\partial v}{\partial x} + \sin \theta \frac{\partial v}{\partial y}$ .

And then using Cauchy Riemann conditions it is convenient to rewrite these two equations. So,  $\frac{\partial u}{\partial r}$  you know write is equal to  $\cos \theta \frac{\partial u}{\partial x}$  you write it as it is. But in place of  $\frac{\partial u}{\partial y}$  its convenient to write  $-\sin \theta \frac{\partial v}{\partial x}$  right so we will see in a moment why this is.

So, and likewise  $\frac{\partial v}{\partial r}$  we write  $\cos \theta \frac{\partial v}{\partial x}$  as it is and then in place of  $\frac{\partial v}{\partial y}$  you just write down  $\frac{\partial u}{\partial x}$  right. So, that is the Cauchy- Riemann conditions we have applied you know here and here you know in place of  $\frac{\partial u}{\partial y}$  and in place of  $\frac{\partial v}{\partial y}$ , we have written  $-\sin \theta \frac{\partial v}{\partial x}$  and  $\frac{\partial u}{\partial x}$  right.

So, once we have these two equations we just add the two, but with a factor of  $i$  associated with the second of these equations. So, it should be  $\frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r}$  when you get  $\cos \theta \frac{\partial u}{\partial x} - \sin \theta \frac{\partial v}{\partial x} + i \cos \theta \frac{\partial v}{\partial x} + i \sin \theta \frac{\partial u}{\partial x}$ . Now, rearranging your  $\cos \theta + i \sin \theta$  you know is multiplied by  $\frac{\partial u}{\partial x}$ .

Then if you pull out an  $i$  then you have a  $\cos \theta$  you know this is  $-\sin \theta$  can be written as  $+i^2 \sin \theta$  and we plot one of these  $i$ 's. So, you have  $\cos \theta + i \sin \theta$  you know both of them have this factor  $\frac{du}{v}$  by  $\frac{dx}{x}$  which comes out and then we see that this factor  $\cos \theta + i \sin \theta$  is common. So, you pull it out and also we use this Euler identity. So,  $\cos \theta + i \sin \theta$  is the same as  $e^{i\theta}$  and we have this expression  $\frac{du}{v}$  by  $\frac{dx}{x}$  plus  $i$  times  $\frac{dv}{v}$  by  $\frac{dx}{x}$ .

So, in other words we have managed to show that  $\frac{du}{v}$  by  $\frac{dr}{r}$  plus  $i$  times  $\frac{dv}{v}$  by  $\frac{dx}{x}$  I mean I write it write you know this right hand side. I have pulled out only this  $\frac{du}{v}$  by  $\frac{dx}{x}$  plus  $i$  times  $\frac{dv}{v}$  by  $\frac{dx}{x}$  is the same as  $e^{i\theta}$  times  $\frac{du}{v}$  by  $\frac{dr}{r}$  plus  $i$  times  $\frac{dv}{v}$  by  $\frac{dx}{x}$  right. So, but what is this quantity? This quantity is nothing but the value of the derivative at that point in Cartesian coordinates.

(Refer Slide Time: 06:57)

The slide content is as follows:

$$\begin{aligned} \frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} &= \cos(\theta) \frac{\partial u}{\partial x} - \sin(\theta) \frac{\partial v}{\partial x} + i \left[ \cos(\theta) \frac{\partial v}{\partial x} + \sin(\theta) \frac{\partial u}{\partial x} \right] \\ &= [\cos(\theta) + i \sin(\theta)] \frac{\partial u}{\partial x} + i [\cos(\theta) + i \sin(\theta)] \frac{\partial v}{\partial x} \\ &= e^{i\theta} \left[ \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \right]. \end{aligned}$$

In other words:

$$\left[ \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} \right] = e^{-i\theta} \left[ \frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} \right].$$

But the value of the derivative in cartesian coordinates is:

$$\frac{df(z)}{dz} = \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x}.$$

Thus the value of the derivative of the function can be written in polar coordinates as:

$$\frac{df(z)}{dz} = e^{-i\theta} \left( \frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} \right).$$

So, the value of the derivative in Cartesian coordinates is this  $\frac{df}{dz}$  is equal to  $\frac{du}{v}$  by  $\frac{dx}{x}$  plus  $i$  times  $\frac{dv}{v}$  by  $\frac{dx}{x}$ . Therefore, the value of the derivative of the function in polar coordinates can be written as simply  $e^{-i\theta}$  times  $\frac{du}{v}$  by  $\frac{dr}{r}$  plus  $i$  times  $\frac{dv}{v}$  by  $\frac{dr}{r}$  right.

So, often it is convenient to work out the value of the derivative directly in polar coordinates right. So, sometimes it is much more tedious to do the check for Cauchy- Riemann conditions in polar in Cartesian coordinates and therefore, it is quite useful to have this polar form ready.

And so, that is what we did in this lecture. We worked out the value of the derivative both in Cartesian coordinates and in polar coordinates.

Thank you.
