Lecture 10

Solutions of Integral Equations by Successive Approximations: Resolvent Kernel

(Refer Slide Time: 00:18)

Ok! So welcome to welcome my friends and here in previous lecture if (you) we have already discussed the successive approximation method to solve Fredholm integral equation of second kind and we have seen this thing that we have  $y(x)$  is equal to see  $f(x)$  plus lambda times  $k(x, t)$  (f of)  $y(t)$  dt not  $f(t)$  it is  $y(t)$  dt d(t) here and we have seen that by approximation here we have created a approximation scheme like this  $y_{n+1}(x)$  equal to  $f(x)$  plus lambda times  $k(x,t)$  and  $y_n(t)$  dt and we have shown that under certain condition here we assume that this kernel  $k(x,t)$  and this function  $f(x)$  both are square integral with function.

And in previous class we have seen the convergence criteria here we have seen that modulus of lambda b is less than 1 then this series is going to be this  $y_n(x)$  will converge to  $y(x)$  absolutely and uniformly so this convergence is uniform here. So here b is basically what b is basically modulus of  $k(x, t)$  whole square dx dt. So here this is the b rotation and if modulus of lambda b is less than 1 this convergence is uniform.

(Refer Slide Time: 01:59)

**Error Estimate**

The series (4) can be written as

$$y(x) = f(x) + \sum_{m=1}^n \lambda^m \int K_m(x, t) f(t) dt + R_n(x).$$

Then from the previous analysis, we find

$$|R_n| \leq MC_1 |\lambda|^{n+1} B^n / (1 - |\lambda|B).$$

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    13

Now we want to show that if we approximate the solution of this by (n plus 1)th approximation here then of course there should be a truncation error we try to see that what should be the truncation here. So here we say that if this series can be written as like this. So here y(x) equal to f(x) m equal to 1 to n lambda m k m(x, t) dt. So this is your general term here and on an x I am writing here after (n plus 1) th term.

So here we can say that this term if we truncate a word y(x) by this n th term we can say that there is a truncation error and that truncation error is bounded by this quantity, modulus of R n m c 1 modulus of lambda n plus 1 b to power n divided by this.

(Refer Slide Time: 02:56)

$$y(x) = f(x) + \lambda \int K(x, t) y(t) dt$$

$$y_{n+1}(x) = f(x) + \lambda \int K(x, t) y_n(t) dt$$

$|\lambda|B < 1$        $y_n \rightarrow y(x)$

$$B = \iint |K(x, t)|^2 dx dt$$

$$R_n(x) = \sum_{m=n+1}^{\infty} \lambda^m \int K_m(x, t) f(t) dt$$

$$|R_n(x)| \leq \sum_{m=n+1}^{\infty} |\lambda|^m \left| \int K_m(x, t) f(t) dt \right| \leq M C_1 \lambda^{n+1}$$

$$\left| \int K_m(x, t) f(t) dt \right|^2 \leq M^2 C_1^2 B^{2m-2}$$

So this we can see it like this that your  $r_n$  is going to be what  $r_n$  is basically our summation your  $m$  equal to 1 to  $n$   $\lambda$  to power  $m$  and it is inside your  $k_m(x, t) f(t) dt$  and oh sorry here limit will start from  $n + 1$ . So it is  $n + 1$  to infinity.

So the modulus of  $R_n(x)$  you can find out by so this is going to be less than or equal to now here it is summation  $m$  equal to  $n + 1$  to infinity modulus of  $\lambda$  to power  $m$  here and modulus of this  $k_m(x, t) f(t) dt$  here this thing, right?

So this we can calculate this quantity we can calculate using previous and this is we can see that this is this will reduce to so here let me write it what is modulus value  $k_m(x, t) f(t) dt$  square of this, so square of this is given as capital  $M$  square and this is what  $c + 1$  square and it is going to be  $b$  to power  $2m - 2$ .

So you can say that this is going to be bounded by  $\lambda$  to power  $m$  this is you can say that that is bounded by say  $m + 1$  and  $p$  to power  $m - 1$ , right? And yeah, so we can say that there is something missing here  $\lambda$  to power  $m$  is also there, is that ok?

Then you can write it here this is what this is the geometric series here whose first term is started at  $m + 1$ . So we can simply write the summation here as first term divided by  $1 -$  common ratio.

Common ratio is basically modulus of  $\lambda$  and  $b$ , right? So you can, you can simplify and you can see that the modulus of  $R_n$  is given by bounded by  $m + 1$  modulus of  $\lambda$  to power  $n + 1$   $b^n$  that is your  $(n + 1)$ th term divided by  $1 -$  common ratio here that is modulus of  $\lambda b$ , ok.

(Refer Slide Time: 05:32)

By changing the order of integration and summation in the Neumann series

$$y(x) = f(x) + \lambda \int \left[ \sum_{m=1}^{\infty} \lambda^{m-1} K_m(x, t) \right] f(t) dt$$
$$= f(x) + \lambda \int \Gamma(x, t; \lambda) f(t) dt \quad (11)$$

where

$$\Gamma(x, t; \lambda) = \sum_{m=1}^{\infty} \lambda^{m-1} K_m(x, t) \quad (12)$$

is called the resolvent kernel. The series (12) is also convergent at least for  $|\lambda|B < 1$ . Hence the resolvent kernel is an analytic function of  $\lambda$ , regular at least inside the circle  $|\lambda| < B^{-1}$ .

BT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    14

Now here we since convergence is uniform here so I can write that this integral and the summation can be interchangeable. So if you remember our solution is given by this Neumann Series  $y(x)$  equal to  $f(x)$  plus  $\lambda$  here we are interchanging the summation and integral sign we are taking summation sign inside and we can write it like this. So here this notation we are calling this as  $\gamma(x,t) \lambda f(t) dt$  where  $\gamma(x, t) \lambda$  is given by defined by this  $\int_0^1 \lambda^{m-1} k_m(x,t)$  here.

I am taking  $\lambda$  here then that is why this  $\lambda$  to power  $m$  is (trunca) appearing here. So we are saying that we are calling this  $\gamma(x, t) \lambda$  as Resolvent Kernel. Again we we can prove that this  $\gamma(x, t) \lambda$  is given by this power series in terms of this  $\lambda$  here and we can say that this says now I am taking function of a  $\lambda$  here . And this convergence we have already seen that it is convergent in the for modulus of  $\lambda$   $b$  is less than 1.

So this is also an analytic function of  $\lambda$  whose radius of convergence is a given by this formula modulus of  $\lambda$  is less than  $b$  inverse,  $b$  is defined here, right?

(Refer Slide Time: 06:54)

The slide is titled "Uniqueness of Resolvent kernel". It contains the following text and equations:

Let equation (1) have, with  $\lambda = \lambda_0$ , two resolvent kernels  $\Gamma_1(x, t; \lambda_0)$  and  $\Gamma_2(x, t; \lambda_0)$ . From the uniqueness of the solution of (1), we have

$$f(x) + \lambda_0 \int \Gamma_1(x, t; \lambda_0) f(t) dt \equiv f(x) + \lambda_0 \int \Gamma_2(x, t; \lambda_0) f(t) dt. \quad (13)$$

Setting  $\psi(x, t; \lambda_0) = \Gamma_1(x, t; \lambda_0) - \Gamma_2(x, t; \lambda_0)$ , we obtain

$$\int \psi(x, t; \lambda_0) f(t) dt \equiv 0. \quad (14)$$

At the bottom of the slide, there are logos for "IIT ROORKEE" and "NPTEL ONLINE CERTIFICATION COURSE", and the number "15" in the bottom right corner.

So here we can say that if solution is unique we can say that not only solution is unique even this resolvent kernel is also unique. So for that let us say that we have two resolvent kernels corresponding to the same solution. And call it gamma 1 and gamma 2 and we try to show that this gamma 1 is equal to gamma 2 for that we just equate  $y(x)$  here which is obtained by gamma 1 and  $y(x)$  which is obtained by this gamma 2.

And since these are equal we can say that these are equal. So  $f(x)$   $f(x)$  will be cancelled out and you can write it that lambda not we are assuming that it is some non zero constant and we are writing this as denoting  $\psi(x, t)$  lambda as difference of these two and we can write it that  $\psi(x, t)$  lambda  $\int f(t) dt$ . Here I am using a particular value lambda 0 for this lambda. And this is true for all function  $f(t)$  here.

(Refer Slide Time: 07:59)

For an arbitrary function  $f(t)$ , let  $f(t) = \psi^*(x, t, \lambda_0)$ , with fixed  $x$ . Which implies

$$\int |\psi(x, t; \lambda_0)|^2 dt = 0$$

which means that  $\psi(x, t; \lambda_0) = 0$ . Hence the resolvent kernel is unique.

BY ROOIKEE INTEL ONLINE CERTIFICATION COURSE 16

So here we can choose this  $f(t)$  as complex conjugate of this  $\psi(x, t; \lambda_0)$ . So since this is true for every  $f(t)$  we can say that even it should be true for its  $f(t)$  which is given as complex conjugate of this side stamp. If we use it then we have this last equation given as 14 is reduced this integral of  $|\psi(x, t; \lambda_0)|^2 dt = 0$ .

So here this is not equality this is equivalent is not correct word it is equality. So here we can say that this is possible only when, when this integrand is unequal equal to 0. So if it is a integrand is unequal to 0 means your this  $\gamma_1$  is unequal to  $\gamma_2$ . So it means that under the condition that modulus of  $\lambda_0$  is less than 1 your solution is unique your resolvent kernel is unique where resolvent kernel is defined by equation number 12, is it ok?

(Refer Slide Time: 09:57)

$$|\gamma(x, \lambda)|^2 \leq \sum_{m=1}^{\infty} \lambda^{m-1} |k_m(x, t)|^2$$

$$|k_m(x, t)|^2 \leq \frac{\int |K(x, \xi)|^2 d\xi \int |k_m(x, t)|^2 d\xi}{\int |K(x, \xi)|^2 d\xi}$$

$$E_1 = \int |K(x, \xi)|^2 d\xi$$

$$C_1 = \int K(x, \xi) dx$$

Now they are certain mode properties corresponding to your resolvent kernel and the solution we just writing here and we say that for every  $l$  to kernel  $k(x, t)$  they correspond a unique resolvent kernel  $\gamma(x, t)$  lambda this uniqueness we have already proved. And which is  $\gamma(x, t)$  lambda is defined by this  $m$  equal to 1 into infinity lambda to power  $m$  minus 1  $k_m(x, t)$ .

And we can prove that this is absolutely and uniformly convergent for all values of  $x$  and  $t$  in the circular modulus of lambda is less than  $b$  inverse and further more we have just proved that if  $f(x)$  is also an  $l^2$  function then the unique  $l^2$  solution of the certain integral equation 1 valid in the circle modulus of lambda less than  $b$  inverse that we have proved in the previous lecture, ok.

So this proves that this  $\gamma(x, t)$  lambda is convergent in this reason I can give you small hint that is all I can simply write it here as this. So here if you look at  $\gamma(x, t)$  lambda it is denoted as summation  $m$  equal to 1 to infinity lambda to power  $m$  minus 1  $k_m(x, t)$ , right? So here we take modulus here and take the square here so this less than or equal to modulus here and square here.

And then you can find out  $k_m(x, t)$  and square of this again using the Cauchy's inequality so which is it is like  $k(x, \xi)$  square  $d\xi$  and here we have  $k_m$  minus 1  $x, t$  square  $d\xi$  and using the bond of this. So that you can do and you can say that now please remember here it is different from  $c_1$ . This is not a  $c_1$  this is infinite quantity but it is different,  $c_1$  is defined by

what ?  $c_1$  is defined as  $k(x, x) \int_a^b t dx$ , so this is your  $c_1$  so we can call this as any quantity let us say this is  $\epsilon_1$ ,  $\epsilon_1$  I am denoting as modulus of  $k(x, x)$  square  $\int_a^b dx$  as some  $\epsilon_1$ .

(Refer Slide Time: 11:35)

**Theorem 3**  
 Let  $\Gamma(x, t; \lambda)$  be the resolvent kernel of a Fredholm integral equation

$$y(x) = f(x) + \lambda \int_a^b K(x, t)y(t) dt.$$

then the resolvent kernel satisfies the integral equation

$$\Gamma(x, t; \lambda) = k(x, t) + \lambda \int_a^b k(x, z)\Gamma(z, t; \lambda) dz.$$

NPTEL ONLINE CERTIFICATION COURSE 18

So using these notations you can prove that this series is also absolutely and uniformly convergent for the same bound that is modulus of lambda less than  $b^{-1}$ , ok. I am not giving any proof of this, ok. Now there is one more theorem which is important to know that if  $\gamma(x, t; \lambda)$  is the resolvent kernel of this Fredholm integral equation then this  $\gamma(x, t; \lambda)$  is also satisfying the (kernel) this integral equation given in terms of  $\gamma(x, t; \lambda)$ .

And define as  $\gamma(x, t; \lambda) = k(x, t) + \lambda \int_a^b k(x, z)\gamma(z, t; \lambda) dz$ . There is one and this is done as Fredholm identities and there is one more Fredholm identities given in terms of  $\gamma(x, t; \lambda)$ . So that we write when it is required, ok. So this is the integral equation satisfied by the resolvent kernel.

(Refer Slide Time: 12:34)

Theorem 4  
The resolvent kernel satisfies the integro-differential equation

$$\frac{\partial \Gamma(x, t; \lambda)}{\partial \lambda} = \int_a^b \Gamma(x, z; \lambda) \Gamma(z, t; \lambda) dz.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 19

Now there is one more theorem which I am writing just for sake of completeness that resolvent kernel satisfy the integro differential equation given by this, ok. Why we are integro differential equation there is a differentiation of gamma(x, t) lambda with respect to lambda is given in terms of integral equation. So that is why it is integro differential equation. So it is just for completeness.

(Refer Slide Time: 12:58)

Example 1  
Solve the integral equation:

$$y(x) = f(x) + \lambda \int_0^1 e^{x-t} y(t) dt. \quad (15)$$

**Solution:** We have

$$K_1(x, t) = k(x, t) = e^{x-t}$$
$$K_2(x, t) = \int_0^1 e^{x-\xi} e^{\xi-t} d\xi = e^{x-t}$$

Proceeding in this way we obtain

$$K_m(x, t) = e^{x-t}.$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 20

Now we try to solve some problem with the help of the theory developed earlier by the way here I just want to say one word for the theory part that before doing any problem we may start attacking in the problem itself but before attacking to any problem we must know that

they exist a solution and not only a solution we should not know that the iterative procedure we are considering that should converge somewhere not only converge it will converge to a unique limit.

That is why we have discussed all the theory part. Now let us see towards our theory and try to discuss these examples. So here we have  $y(x)$  equal to  $f(x)$  plus  $\lambda \int_0^1 e^{-x-t} y(t) dt$ . So here your kernel is given in terms of  $e^{-x-t}$ . So  $k_1$  is defined as this you can define  $k_2(x, t)$  as like this. So I hope you will remember the formula here.

(Refer Slide Time: 13:57)

So what is your so  $k_1(x, t)$  is same as  $k(x, t)$ , so  $k(x, t)$  is given as  $e^{-x-t}$  and  $k_2(x, t)$  is basically what  $k_2(x, t)$  is basically integration of  $k(x, \xi) k(\xi, t) v(x, \xi)$ . Please remember here this starting point  $x$  is a starting point here end point here is a end point here. And this  $\xi$  is the integral variable. So you can use this formula and you can find out  $k_2(x, t)$  and if you simplify it is given by  $e^{-x-t}$ .

(Refer Slide Time: 14:34)

**Example 1**

Solve the integral equation:

$$y(x) = f(x) + \lambda \int_0^1 e^{x-t} y(t) dt. \quad (15)$$

**Solution:** We have

$$K_1(x, t) = k(x, t) = e^{x-t}$$

$$K_2(x, t) = \int_0^1 e^{x-\xi} e^{\xi-t} d\xi = e^{x-t}$$

Proceeding in this way we obtain

$$K_m(x, t) = e^{x-t},$$

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    20

Here a is 0 and b is 1 and if we proceed in a similar way we can say that  $k_m(x, t)$  is given by  $e^{x-t}$ . So once we have (14:44) iterations for this kernel then we can write we can find out resolvent kernel.

(Refer Slide Time: 14:54)

and the resolvent kernel

$$\Gamma(x, t; \lambda) = \sum_{m=1}^{\infty} \lambda^{m-1} K_m(x, t)$$

$$= e^{x-t} (1 + \lambda + \lambda^2 + \dots) = e^{x-t} / (1 - \lambda)$$

The series  $(1 + \lambda + \lambda^2 + \dots)$  converges only for  $|\lambda| < 1$ . The solution  $y(x)$  can be written as

$$y(x) = f(x) - [\lambda / (\lambda - 1)] \int_0^1 e^{x-t} f(t) dt. \quad (16)$$

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    21

Resolvent kernel is defined as  $\sum_{m=1}^{\infty} \lambda^{m-1} k_m(x, t)$  we can we have already find out  $k_m(x, t)$  as  $e^{x-t}$ .

And if you look at this is geometric series with common ratio  $\lambda$  so here this will converge provided that modulus of  $\lambda$  is less than 1 and we can say that  $\Gamma(x, t)$

lambda is given by e to power x minus t divided by 1 minus lambda and solution is given by y(x) f(x) minus lambda divided by lambda minus 1 0 to 1 e to power x minus t f(t) dt.

So once you know your n th iteration for kernel you can define resolving kernel and you can write down your solution in terms of resolvent kernel and in this case it is coming out to be given by equation number 16, is that ok.

(Refer Slide Time: 15:37)

**Example 2**

Determine the resolvent kernel for the equation

$$y(x) = f(x) + \lambda \int_{-1}^1 (1+x)(1-t)y(t)dt. \quad (17)$$

**Solution:** We have

$$K_1(x, t) = K(x, t) = (1+x)(1-t)$$

$$K_2(x, t) = \int_{-1}^1 k(x, \xi)k_1(\xi, t)d\xi = \frac{2}{3}(1+x)(1-t)$$

$$K_3(x, t) = \int_{-1}^1 k(x, \xi)k_2(\xi, t)d\xi = \left(\frac{2}{3}\right)^2(1+x)(1-t)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 22

Now let us move to one more non trivial I can say this is quite trivial because here k 1(x, t) is coming out to be e to the power x minus t and all these k 1 to k n is coming out to be e to power x minus t.

Let us take some more difficult problem here and we say that here as he does the second problem here your k(x, t) is given by 1 plus x into 1 minus t again it is not very difficult but anyway it is not too easy also. So here a is equal to minus 1 and b is equal to 1. And again we want to write this solution here. So here k 1(x, t) is same as k(x, t) so it is (1 plus x) (1 minus t) 1 minus t here.

And you can find out k 2(x, t) is what a to b k(x i) k 1(x i) t b (x i). So when you solve this it is simple integration and you can say that it is 2 by 3 (1 plus x) (1 minus t). And if you keep on doing this you can see that this is a kind of pattern we are getting that k 3 is basically 2 by 3 square (1 plus x) (1 minus t). So if you look at here 3 corresponding to the second power of this quantity 2 by 3.

So if you define you will get  $k_m(x, t)$  is defined as  $(2/3)^m (1+x)(1-t)$  and if you find out the resolvent kernel, resolvent kernel is given by this and you can put the value of  $k_m(x, t)$  here and you can say that it is simple  $(1+x)(1-t)$  and this summation. Now this is again a geometric series in terms of  $2/3$ . So here we can say that this will converge and summation is given by  $1/(1 - \text{common ratio})$  that is  $3/1$ .

And this will converge only when this quantity is less than 1 or I can say that modulus of  $2/3$  in this particular case your  $\gamma(x, t)$  is given by this quantity. So  $\gamma(x, t)$  is given by this provided modulus of  $2/3$  is less than 1. So once you know your  $\gamma(x, t)$  you can find out your solution. And ok, so you can write all this solution here, ok.

(Refer Slide Time: 17:42)

**Example 3**

Find the resolvent kernel for

$$y(x) = 1 + \lambda \int_0^1 (1 - 3xt)y(t) dt. \quad (18)$$

**Solution:** Here

$$K_1(x, t) = K(x, t) = 1 - 3xt,$$

$$K_2(x, t) = \int_0^1 K(x, z)K_1(z, t) dz = \int_0^1 (1 - 3xz)(1 - 3zt) dz$$

$$= 1 - 3/2(x + t) + 3xt.$$

IT MOOVRKE    NPTEL ONLINE CERTIFICATION COURSE    25

Now let us discuss example number 3 here  $y(x)$  equal to  $1 + \lambda \int_0^1 (1 - 3xt)y(t) dt$ . If you remember we have discussed this kind of problem for  $f(x)$  for general  $f(x)$  there we have assumed  $1$  is equal to  $f(x)$  if you look at this is the example with the separable kernel here  $k(x, t)$  is given by  $1 - 3xt$ . And we have already discussed the solution procedure in the lecture of a separable kernel. We have already solved for.

Now here we are solving for a particular case when  $f(x)$  is equal to 1 here, so again as we want to find out say resolvent kernel of this so for that  $k_1(x, t)$  is same as  $k(x, t)$  it is given by  $1 - 3xt$ . Similarly you can find out  $k_2(x, t)$  and it is given by this formula  $k_2(x, t) = \int_0^1 k(x, z)k_1(z, t) dz$  you don't worry about these  $k(x, z)k_1(z, t)$  whatever, you simply remember only this thing

that the first variable here will be here, and the last the second variable is will be here. Here it is your integral variable ok. So using this formula you can write down  $k_2(x, t)$  like this.

(Refer Slide Time: 19:05)

$$K_3(x, t) = \int_0^1 K(x, z)K_2(z, t)dz = \int_0^1 (1 - 3xz)(1 - 3/2(z + t) + 3zt)dz$$

$$= 1/4(1 - 3xt) = 1/4K_1(x, t).$$

$$K_4(x, t) = \int_0^1 K(x, z)K_3(z, t)dz = \int_0^1 (1 - 3xz) \frac{1}{4}(1 - 3zt)dz$$

$$= 1/4(1 - 3/2(x + t) + 3xt) = 1/4K_2(x, t).$$

Similarly  $K_5(x, t) = (1/4)^2 K_1(x, t)$ ,  $K_6(x, t) = (1/4)^2 K_2(x, t)$ ,  $K_7 = (1/4)^3 K_1(x, t)$  and so on.

Now

$$\Gamma(x, t; \lambda) = \sum_{m=1}^{\infty} \lambda^{m-1} K_m(x, t)$$

$$= K_1(x, t) + \lambda K_2(x, t) + \lambda^2 K_3(x, t) + \lambda^3 K_4(x, t) + \dots$$

IT ROORKEE    NPTEL ONLINE CERTIFICATION COURSE    26

Similarly you can calculate  $k_3(x, t)$ ,  $k_4(x, t)$  and so on. And when you calculate  $k_3(x, t)$  it is coming out to be  $1/4 k_1(x, t)$ . Similarly  $k_4(x, t)$  is given in terms of  $k_2(x, t)$  so it is  $1/4 k_2(x, t)$ . If you keep on doing this then you can see that all odd number of iterations  $k_3$ ,  $k_5$ ,  $k_7$  all are written in terms of  $k_1(x, t)$ .

Similarly your even say  $k_2$ ,  $k_4$ ,  $k_6$  all are written in terms of even that is  $k_2(x, t)$ . So I can write this write resolvent kernel as  $\Gamma(x, t; \lambda)$  as  $\lambda^{m-1} k_m(x, t)$  as this series  $k_1(x, t)$  plus  $\lambda k_2(x, t)$  and so on and there we can put the value of  $k_3$ ,  $k_4$  and so on in terms of  $\lambda^1$  and  $\lambda^2$ . So I can write it like this.

(Refer Slide Time: 20:03)

$$\begin{aligned}
 \Gamma(x, t, \lambda) &= K_1(x, t) + \lambda^2 K_3(x, t) + \lambda^4 K_5(x, t) + \dots \\
 &\quad \lambda [K_2(x, t) + \lambda^2 K_4(x, t) + \lambda^4 K_6(x, t) + \dots] \\
 &= K_1(x, t) + \frac{\lambda^2}{4} K_1(x, t) + \frac{\lambda^4}{4^2} K_1(x, t) + \dots \\
 &\quad \lambda [K_2(x, t) + \frac{\lambda^2}{4} K_2(x, t) + \frac{\lambda^4}{4^2} K_2(x, t) + \dots] \\
 &= K_1(x, t) \left[ 1 + \frac{\lambda^2}{4} + \left( \frac{\lambda^2}{4} \right)^2 + \dots \right] \\
 &\quad + \lambda K_2(x, t) \left[ 1 + \frac{\lambda^2}{4} + \left( \frac{\lambda^2}{4} \right)^2 + \dots \right]
 \end{aligned}$$

provided  $\lambda^2 < 4$  or  $|\lambda| < 2$

So  $k_1(x, t)$  as it is  $\lambda^2 k_3(x, t)$  and this is  $k_2(x, t)$  and then we are writing all odd terms together and all even terms together. So here when you use the value of  $k_3(x, t)$  it is coming out to be  $\frac{1}{4} k_1(x, t)$ , ok. Similarly  $k_5(x, t)$  is you just look at your calculation  $k_5(x, t)$  is  $\frac{1}{4^2} k_1(x, t)$  similarly  $k_7$  is  $\frac{1}{4^3} k_1(x, t)$ . So using this you can find out the summation and it is coming out to be  $k_1(x, t)$  times this and  $\lambda k_2(x, t)$  times the same series if you look at there is same series here.

And if you look at this is a geometric series with the common ratio  $\lambda^2/4$ , so this will converge provided that modulus  $\lambda^2/4$  is less than 1 or you can say that modulus of  $\lambda$  is less than 2 so you keeping this thing in mind that modulus of  $\lambda$  is less than 2.

(Refer Slide Time: 21:07)

$$\Gamma(x, t; \lambda) = (K_1(x, t) + \lambda K_2(x, t)) \left[ 1 + \frac{\lambda^2}{4} + \left( \frac{\lambda^2}{4} \right)^2 + \dots \right]$$

$$= (K_1(x, t) + \lambda K_2(x, t)) \frac{1}{1 - (\lambda^2/4)}$$

$$= \frac{4}{4 - \lambda^2} \left[ 1 + \lambda - \frac{3}{2}x\lambda - 3t \left( x + 1/2\lambda - x\lambda \right) \right].$$

Hence the solution of (18) can be written as

$$y(x) = f(x) + \lambda \int_0^1 \Gamma(x, t; \lambda) f(t) dt$$

You can simplify and this written as  $k_1(x, t) + \lambda k_2(x, t)$  into  $1 + \frac{\lambda^2}{4} + \left(\frac{\lambda^2}{4}\right)^2 + \dots$ . And if you simplify using  $k_1(x, t)$  and  $k_2(x, t)$  it can be given by this. So here once you have  $\Gamma(x, t; \lambda)$  you can write down the solution as  $y(x) = f(x) + \lambda \int_0^1 \Gamma(x, t; \lambda) f(t) dt$  we can put it here provided that modulus of  $\lambda$  is less than 2.

So your solution if you simplify  $f(x)$  is given as 1 here so putting the value 1 here you can see that  $y(x)$  is equal to this quantity  $\frac{4}{4 - \lambda^2} \left[ 1 + \lambda - \frac{3}{2}x\lambda - 3t \left( x + 1/2\lambda - x\lambda \right) \right]$  provided this condition modulus of  $\lambda$  less than 2. And we can say that this will converge only when we are modulus of  $\lambda$  less than 2.

So it means that we don't have any criteria to say that if what happen if modulus of  $\lambda$  equal to 2 or modulus of  $\lambda$  greater than 2, but if we remember the same problem we have discussed in the case of separable kernel there we have we are able to find out the solution of this in the case when modulus of  $\lambda$  is equal to 2 or you can say  $\lambda = 2$  or  $\lambda = -2$  and even when modulus of  $\lambda$  is not equal to 2 modulus of  $\lambda$  is not equal to 2.

So it means that here this is a quite method of successive approximation is quite useful but not in all case. Here I can say that this is in this particular example your method of separable kernel is quite useful. That gives you solution for all values of modulus of  $\lambda$  here in fact

you can check that for modulus of lambda less than 2 the method of separable kernel and method of successive approximation both will match.

But this will not give any result for modulus of lambda greater than 2 or modulus of lambda equal to 2, so in that case this since it is a problem of separable kernel so we suggest that whenever we have problem of separable kernel we always use the method of separable kernel and we may say why it is happening like this why we are not able to get that the entire reason for modulus of lambda.

(Refer Slide Time: 23:56)

So if you remember in a method of separable kernel we are getting solution like this , we are getting solution like y(x) equal to sum of f(x) here it is 1 plus some lambda times c 1 minus 3 c 2 x kind of thing if you remember we have we can do it like this if you apply a method of successive separable kernel you can get it solution like this.

And when you find out your c 1 and c 2 then you have say d lambda and here we have c 1 and c 2 and it is some integration f(x) d(x) plus integration x f(x) dx , right? 0 to 1 here limit is 0 to 1 here and you can find out your c 1 and c 2. So if you remember I can say that here your lambda is there right so here we can say that it is given in terms of c 1 c 2 you can find out in terms of your numerator and denominator numerator is also given in terms of lambda denominator also given in terms of lambda.

So you can say that it is kind of some function during lambda divided by some function given in terms of lambda and if you divide it then you will have a function in terms of you can write

it in terms of say  $\lambda$  some polynomial functions in terms of  $\lambda$ . So in successive approximation we are writing our solution in terms of your series in terms of  $\lambda$ .

So if you say that here if we do this then this relation will be valid when modulus of  $\lambda$  is say here we have some radius of convergence here we have some radius of convergence so this whole expression is valid when we have modulus of  $\lambda$  less than or equal to say any radius of convergence here, so if you remember this will converge when modulus this  $\lambda$  is non zero when modulus of  $\lambda$  is less than 2.

So that is why this method of separable kernel and method of approximation successive approximation will match when modulus of  $\lambda$  is less than 2, is that ok. So but we suggest that whenever we have a problem with the separable kernel we start solving with the help of method with the given in the lecture solving solution of a integral equation with the help of separable kernel, is it ok.

So thanks for listening us and we will meet again in next lecture , Thank you!
