Fredholm Integral Equations with Symmetric kernels: Hilbert Schmidt theory.

(Refer Slide Time: 0:51)

Theorem 2: (HILBERT THEOREM) Every symmetric kernel with a non-zero norm has at least one eigenvalue.

Theorem 3: The eigenfunctions corresponding to distinct eigenvalues are orthogonal to each other.

Proof: Let $y_1(x)$ and $y_2(x)$ be the eigenfunctions corresponding to two distinct eigenvalues λ_1 and λ_2 of the homogeneous Fredholm equation

$$y(x) = \lambda \int_a^b K(x, s)y(s)ds, \quad (5)$$

and suppose that kernel $K(x, t)$ is symmetric. Here we note that $\lambda = 0$ can not be an eigenvalue since it gives the trivial solution $y(x) \equiv 0$. The functions y_1 and y_2 satisfies the equation (5)

$$y_1(x) = \lambda_1 \int_a^b K(x, s)y_1(s)ds \quad (6)$$
$$y_2(x) = \lambda_2 \int_a^b K(x, s)y_2(s)ds \quad (7)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 4

Hello friends, welcome to the lecture of integral equation, fredholm integral equation with the symmetric kernel. So if you look at, if you remember, we have discussed certain theorem corresponding to fredholm integral equation which symmetric kernel. So 1st theorem we have discussed is that if a kernel is symmetric, then all its iterated kernels are also symmetric. And 2nd result which is a kind of hunting license to start with, that is every symmetric kernel with a nonzero norm has at least one eigenvalue. So this is the beginning point by which we want to start our theory.

(Refer Slide Time: 1:16)

Theorem 4: The eigenvalues of a Fredholm integral equation with a real symmetric kernel are real.

Proof: Let λ_1 be an imaginary eigenvalue corresponding to a complex eigenfunction $y_1(x)$. Then the complex conjugate number $\bar{\lambda}_1$ will be an eigenvalue corresponding to an eigenfunction $\bar{y}_1(x)$, which is the complex conjugate of $y_1(x)$. Hence using (8), we obtain

$$(\lambda_1 - \bar{\lambda}_1) \int_a^b y_1(x) \bar{y}_1(x) dx = 0. \quad (9)$$

If $\lambda_1 = \alpha_1 + i\beta_1$ and $y_1(x) = f_1(x) + ig_1(x)$. Then (9) gives

$$2i\beta_1 \int_a^b (f_1^2 + g_1^2) dx = 0.$$

Since $y_1(x) \neq 0$, the integral cannot vanish unless the imaginary part of λ_1 i.e. β_1 must vanish. Hence we conclude that the eigenvalues of a Fredholm integral equation with a real symmetric kernel are real.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 7

Theorem 5: The multiplicity of any non-zero eigenvalue is finite for every symmetric kernel for which $\int_a^b \int_a^b |K(x, t)|^2 dx dt$ is finite.

Proof: Let the functions $\phi_{1\lambda}(x), \phi_{2\lambda}(x), \dots, \phi_{n\lambda}(x) \dots$ be the L.I. eigenfunction which correspond to a nonzero eigenvalue λ . Using the Gram-schmidt procedure, we can find linear combinations of these functions which form an orthonormal system $\{u_{k\lambda}(x)\}$. Then the corresponding complex conjugate system $\{\bar{u}_{k\lambda}(x)\}$ also forms an orthonormal system.

Let $K(x, t) \sim \sum_i a_i \bar{u}_{i\lambda}(t)$,

where $a_i = \int_a^b K(x, t) u_{i\lambda}(t) dt = \lambda^{-1} u_{i\lambda}(x)$. (10)

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

So 3rd is that if we have more than one more than one Eigen functions corresponding to distinct eigenvalues, then they are orthogonal to each other. And theorem 4 says that the eigenvalues of a fredholm integral equation with the real symmetric kernel are real, okay. And next result is which we have discussed states that the multiplicity of any nonzero eigenvalue is finite. So multiplicity is the number of linearly independent Eigen functions corresponding to a given eigenvalue is always finite, provided we have a symmetric kernel and this quantity is finite.

(Refer Slide Time: 2:22)

Theorem 6: The eigenvalues of a symmetric L_2 - kernel form a finite or an infinite sequence $\{\lambda_n\}$ with no finite limit point.

Theorem 7: Let the sequence $\{\phi_n(x)\}$ be all the eigenfunctions of a symmetric L_2 kernel $K(x, t)$ with $\{\lambda_n\}$ as the corresponding eigenvalues. Then the truncated kernel

$$K^{(n+1)}(x, t) = K(x, t) - \sum_{m=1}^n \frac{\phi_m(x)\bar{\phi}_m(t)}{\lambda_m}$$

has the eigenvalues $\lambda_{n+1}, \lambda_{n+2}, \dots$, to which correspond the eigenfunctions $\phi_{n+1}(x), \phi_{n+2}(x), \dots$. The kernel $K^{(n+1)}(x, t)$ has no other eigenvalues or eigenfunctions.

Theorem 8: A necessary and sufficient condition for a symmetric L_2 kernel to be separable is that it have a finite number of eigenvalues.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

So this we have discussed in previous lecture, now let us utilise the proof of this theorem 5 to prove one more result which says that the eigenvalues of a symmetric L_2 kernel form a finite or infinite sequence with no finite limit point. It means that when we have a sequence of Eigen functions, if it is finite, then no problem, but if it is infinite, then we do not have finite limit point, so they will converge to infinity. So for that we just look at that, suppose we have a sequence, say λ_i , so we have a sequence say λ_i and the corresponding sequence Eigen functions we are denoting as Φ_i of x .

So without loss of generality we can assume that all the Φ_i are all orthonormalized by a gram Schmidt process. Now if you remember, in previous proof, we have simply approximated your k of x, t as a summation your $a_i \Phi_i$ here. So I is equal to whatever I_x

we have. So here we are taking the summation of over a_i . So this is the beginning point here we are assuming. So here I am assuming that $U_i \bar{\lambda}_i$ is your Eigen functions corresponding to λ_i . So if you drop this notation λ_i , then you can say that it is nothing but this.

So here we are assuming that $k(x,t)$ is approximated by $\sum a_i U_i \bar{\lambda}_i$. So here $U_i \bar{\lambda}_i$ is the corresponding, so Eigen functions corresponding to your eigenvalues λ_i , is that okay. So in the same way you can define your a_i , a_i is basically $\int_a^b k(x,t) U_i(t) dt$. So I am dropping this λ_i because we are considering all the Eigen, eigenvalues. So if you remember that U_i is the Eigen functions corresponding to say λ_i eigenvalues. So here I am assuming that if we have repeated say eigenvalues, we count them as λ_1 , λ_2 and so on.

(Refer Slide Time: 4:29)

$$\{\lambda_i\} \quad \{U_i(x)\}$$

$$K(x,t) \approx \sum_i a_i U_i(x)$$

$$a_i = \int_a^b k(x,t) U_i(t) dt = \frac{1}{N_i} U_i(x)$$

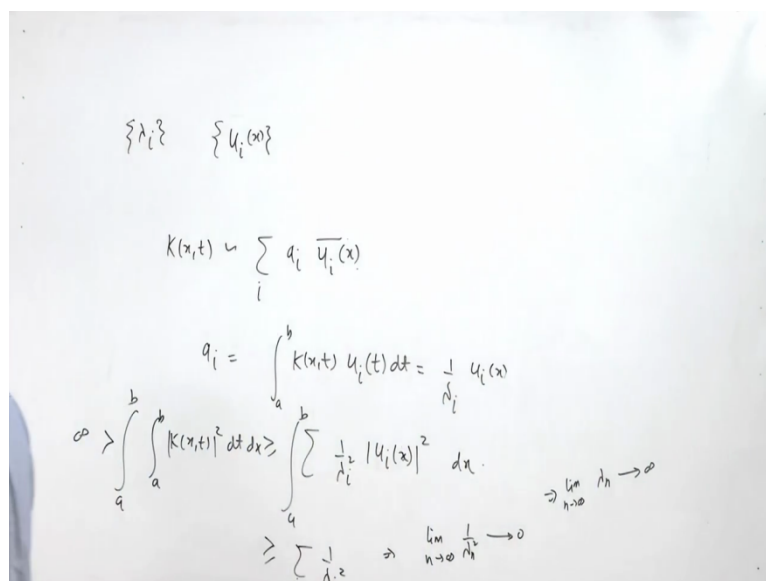

So it may happen that λ_1 , λ_2 may be equal and same as λ , but we are counting all the eigenvalues, okay. So we are saying that this U_i is the Eigen functions corresponding to λ_i . So here a_i is nothing but $\lambda_i^{-1} U_i(x)$. So here I am writing here, let me use this notation, since I am using this, let us assume this, this Φ_i is replaced by your U_i . So this is U_i , x is the Eigen functions corresponding to this λ_i , so I can write it like this. So here we have say U_i , because if this is Eigen functions, then these are also Eigen functions, okay.

(Refer Slide Time: 5:30)

So here I can approximate $k(x,t)$ by this. So here a_i is basically what, a_i is a to b , your k of x and U I t dt . Now this is, since by the property of Eigen functions, this is 1 upon λ_i , your U I x , is that okay. So here a_i you can get it like this, 1 upon λ_i U I x . Then again we can use Bessel's inequality and you can have this property, this equation 11. So along equation number 11, you have this a to b k of x t square dt is greater than or equal to summation 1 upon λ_i square and it is what, modulus of U I t square, this is X I think, so this is x here.

(Refer Slide Time: 6:06)

Okay, so now, again now let us, again integrate with respect to x . So a to b dx here, then here we have a to b t of x , right. And we simply assuming, okay. This I can consider, since this U I

x and all normalised, then I can write this as, this is greater than equal to summation 1 upon lambda I square. Is that okay. So let me use the, okay. So here we have this thing. Is that okay. Now, if this quantity is finite, okay so here is this quantity is finite, then we can say that, okay, let me write it here. Then this series, summation 1 upon lambda I square is sum is going to be finite.

Now sum is going to be finite means you are infinite series of 1 by lambda I square is convergent series. And if you remember, there is a small result that if a series converges, then its nth term is tending to 0 as n tending to infinity. So it means that, this implies that limit n tending to infinity, your 1 upon lambda n square is basically tending to 0. Or equivalently we can say that, this implies that limit n tending to infinity, your lambda n is going to be infinity. So there are only 2 possibilities that this sum is finite, if this sum is finite, no problem and if this sum is not finite, then we can use this property of convergent series which says that your nth term is tending to 0, it means that your lambda n is tending to infinity.

(Refer Slide Time: 8:18)

Theorem 6: The eigenvalues of a symmetric L_2 -kernel form a finite or an infinite sequence $\{\lambda_n\}$ with no finite limit point.

Theorem 7: Let the sequence $\{\phi_n(x)\}$ be all the eigenfunctions of a symmetric L_2 kernel $K(x, t)$ with $\{\lambda_n\}$ as the corresponding eigenvalues. Then the truncated kernel

$$K^{(n+1)}(x, t) = K(x, t) - \sum_{m=1}^n \frac{\phi_m(x)\bar{\phi}_m(t)}{\lambda_m}$$

has the eigenvalues $\lambda_{n+1}, \lambda_{n+2}, \dots$, to which correspond the eigenfunctions $\phi_{n+1}(x), \phi_{n+2}(x), \dots$. The kernel $K^{(n+1)}(x, t)$ has no other eigenvalues or eigenfunctions.

Theorem 8: A necessary and sufficient condition for a symmetric L_2 kernel to be separable is that it have a finite number of eigenvalues.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 10

So it means that either your, so this proves this thing that the eigenvalues of a symmetric L_2 kernel form a finite, if it is finite set, fine, or if it is an infinite sequence with no finite limit point. Now this is a rough sketch of the proof, the exact proof ((8:24) proof of this book is, this proof is given in the book by RP kawal, linear integral equation. So now let us move little bit further, which says that theorem 7, it says what, let the sequence $\Phi_n x$ be all the Eigen functions of the symmetric L_2 kernel $k x t$ with λ_n as the corresponding Eigen values.

So here we have, we are able to calculate all the Eigen values and Eigen functions. Then with the help of this we try to define new quantity, which is known as truncated kernel. Which is what, if it is 1st kernel, so it is $k_1(x,t)$ and your $k_2(x,t)$ is basically $k(x,t) - k_1(x,t)$ - this quantity $\phi_1(x)\phi_2(x) + \dots + \phi_m(x)\phi_m(x)$. So it is kind of, we are approximating your kernel $k(x,t)$ by the this thing.

(Refer Slide Time: 9:21)

$\{\lambda_i\} \quad \{u_i(x)\}$
 $K(x,t) \sim \sum_i q_i \overline{u_i(x)}$
 $q_i = \int_a^b K(x,t) u_i(t) dt = \int_a^b u_i(x)$
 $\int_a^b \int_a^b |K(x,t)|^2 dx dt \geq \sum_i \frac{1}{\lambda_i} \int_a^b |u_i(x)|^2 dx$
 $\geq \sum_i \frac{1}{\lambda_i^2} \Rightarrow \lim_{n \rightarrow \infty} \frac{1}{\lambda_n^2} \rightarrow 0$
 $\Rightarrow \lim_{n \rightarrow \infty} \lambda_n \rightarrow \infty$

So here basically we are doing like this. Is that okay. So here we try to find out, say as accurate as possible. So here we are truncating I equal to 1, 1st approximate is 2, 3, and so on. So here we are defining that nth +, n+1th place, it is given by this. So $k(x,t) - m$ equal to 1 to n, $\phi_m(x)$ into some constant, that constant I am writing as $\phi_m(x)$ upon λ_m . So it is kind of approximation of $k(x,t)$ with the help of m, 1st m Eigen functions. So we call it n+1 th truncation of this $k(x,t)$. So this is known as truncated kernel.

Now we can prove that this truncated kernel has the eigenvalues λ_{n+1} , λ_{n+2} and so on, which is corresponding to $\phi_{n+1}(x)$, $\phi_{n+2}(x)$ Eigen functions. So and this kernel will not have any other eigenvalues or any other Eigen functions. So this is corresponding, so it means that if we already know that eigenvalue is an Eigen function, then we can always find out eigenvalues and Eigen functions corresponding to this truncated kernel. Now what is the use of this, we are trying to, with the help of this we are trying to approximate your symmetric kernel with the help of this kind of separable kernel kind of thing.

So here if you remember there is a result in separable kernel, that if we have a separable kernel, then eigenvalues are finite eigenvalues. Now here if I look at that theorem 8, which says that, a necessary and sufficient condition for asymmetric L_2 kernel to be separable is that it have a finite number of eigenvalues. So it means that, this is an if and only if result, that if we have finite number of eigenvalues, then it means that at some point this process will stop. So it means that suppose we have say, we have only n eigenvalues, then we can have say only m Eigen functions.

So it means that at $kn + 1$ th stage, this is nothing but, we cannot get $kn + 1$ xt, so it is simply 0. So in that case your k xt is written as m equal to 1 to n $\phi_m(x)$, $\phi_m(t)$ λ_m . Or we can say that this is nothing but given in terms of separable form. So if we have only finitely many Eigen values, we can say that in that case your k xt is given by this separable form. Or if I say that we do not have, if it is separable, then we already know that we have only finite number of eigenvalues. So if it is finite number of eigenvalues, then it is separable, if it is separable, then we have only finitely many eigenvalues, that we have already done.

So here with the help of theorem 7 we can say that if we have finite number of eigenvalues, then k xt can be written as this kind of form, which is nothing but a separable form for this k xt. So that it means that a symmetric L_2 kernel is separable if and only if we have finite number of eigenvalues, okay. So now let us move to the next result which is a very very important result of Hilbert Schmidt, known as Hilbert Schmidt theorem. It says that, again we are taking this without proof but statement is very very important.

(Refer Slide Time: 13:12)

Hilbert-Schmidt Theorem

Let

$$f(x) = \int K(x, t)g(t)dt \quad (12)$$

where $K(x, t)$ is a symmetric L_2 -kernel and $g(t)$ is a L_2 -function, then $f(x)$ can be expanded in an absolutely and uniformly convergent Fourier series with respect to the orthonormal system of eigenfunctions ψ_1, ψ_2, \dots of the kernel K

$$f(x) = \sum_{m=1}^{\infty} f_m \psi_m(x), \quad f_m = (f, \psi_m). \quad (13)$$

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 11

Let us say that if we have a function f of x , which is given by $\int_a^b k(x,t)g(t) dt$, we can say it is generated by a kernel k and a function g . Here we are assuming that this k kernel k is symmetric L_2 kernel and g also we are assuming that it is L_2 function. Then Hilbert Schmidt theorem says that, then this function f of x which is generated by this k and g can be expanded in an absolutely and uniformly convergent Fourier series with respect to orthonormal system of Eigen functions ψ_1, ψ_2, \dots of the kernel k . That means that, what it says, let me explain in a little bit detailed manner.

(Refer Slide Time: 14:00)

$$f(x) = \int_a^b K(x,t)g(t) dt$$

$$K \in L_2$$

$$g \in L_2 \Rightarrow f(x) = \sum_{m=1}^{\infty} a_m \phi_m(x)$$

$$\phi_m(x) = \lambda_m \int_a^b K(x,t) \phi_m(t) dt \quad \psi_1, \psi_2, \dots$$

$$\Rightarrow f(x) = \sum_{m=1}^{\infty} a_m \psi_m(x)$$

$$a_m := a_m = \int_a^b f(x) \psi_m(x) dx$$

It means that if we have f of x is equal to your $\int_a^b k(x,t)g(t) dt$, so here we are assuming that $k(x,t)$ belongs to L_2 and similarly your $g(t)$, k and g , both belongs to L_2 . Then Hilbert Schmidt theorem says that $f(x)$ can be written as summation of some $a_m \phi_m(x)$ and summation over this m , m is say 1 to infinity. Now what is this ϕ_m , so here ϕ_m is the Eigen function corresponding to this kernel $k(x,t)$. Means what, that it satisfies this property, that $\phi_m(x)$ is equal to $\lambda_m \int_a^b k(x,t) \phi_m(t) dt$.

So it means that that this $\phi_m(x)$ is basically Eigen function corresponding to some eigenvalues for let us say that λ_m and it satisfies this property. And in addition we are just assuming that this can be orthonormalized to say ψ_1, ψ_2, \dots , ψ_1, ψ_2, \dots and so on. So here we can write this as $f(x) = \sum_{m=1}^{\infty} a_m \psi_m(x)$. Now what is the difference between this and this, difference between this and this is that here it is Eigen functions, now by Gram Schmidt orthonormalization, we can convert into new systems having equal number of elements here but now with the property that they are orthonormalized, is that okay.

So it means that $f(x)$ can be written as $\sum a_m \psi_m(x)$ and here a_m you can write it as $\int_a^b f(x) \psi_m(x) dx$. And just for simplicity we are writing this as f_m , we are denoting this as f_m . So if you look at, look at equation number 13, it says that if we have this function which is given by this, then this $f(x)$ can be represented as this infinite series which is absolutely and uniformly convergent. So here f_m is given by this $\int_a^b f(x) \psi_m(x) dx$ which is denoted by this, $\int_a^b f(x) \psi_m(x) dx$. So this is the inner product we are defining as $\int_a^b f(x) \psi_m(x) dx$, is that okay.

(Refer Slide Time: 17:26)

The Fourier coefficients of the function $f(x)$ are related to the Fourier coefficients g_m of the function $g(x)$ by the relations

$$f_m = g_m / \lambda_m, \quad g_m = (g, \psi_m), \quad (14)$$

where λ_m are the eigenvalues of kernel K .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So these coefficients are known as fourier coefficients here and then this fourier coefficient f_m is related to fourier coefficient corresponding to g . So here I can say that this f_m is given by g_m divided by λ_m , where g_m is the fourier coefficient of g and λ_m are the eigenvalues corresponding to say ψ_m and it is eigenvalues of the kernel k . This is not very difficult here, so what we can do here is , to find out this relation 14, f_m equal to g_m divided by λ_m , what we can do here, we have this. Then we simply multiply by say $\psi_m(x)$ and then use a property of orthogonality, let me write it here, we have this, okay.

(Refer Slide Time: 18:30)

$$f(x) = \int_a^b K(x,t) g(t) dt := K g.$$

$$b_m = \langle f, \phi_m \rangle = \langle K g, \phi_m \rangle = \langle g, K^* \phi_m \rangle = \langle g, K \phi_m \rangle$$

$$= \langle g, \frac{\phi_m}{\lambda_m} \rangle = \frac{1}{\lambda_m} \langle g, \phi_m \rangle = \frac{g_m}{\lambda_m}.$$

$$\phi_m(x) = \lambda_m \int_a^b K(x,t) \phi_m(t) dt \quad \psi_1 \dots \dots$$

$$\Rightarrow f(x) = \sum_{m=1}^{\infty} a_m \psi_m(x)$$

$$b_m := a_m = \int_a^b f(x) \psi_m(x) dx$$

So here let us say we have this, we have say f of x ϕ_m here, so here let me write it $f \phi_m$, right. So this I can write it as $f \phi_m$, f is what, let me denote this as kg , so this is denoted as, defined as k operating on g , so this is kind of an operator on this. So k on g , kg is defined as this, okay, limit is say a to b , so $kg \phi_m$ of m . So this you can prove that this is same as $g k$ star and ϕ_m . Now since k star is same as k , because we are assuming that it is a symmetric kernel, then it is nothing but gk of ϕ_m .

Now we already know that $k \phi_m$ means this, k x t ϕ_m dt . So this is going to be ϕ_m x divided by λ_m . So this is what, this is nothing but g , your ϕ_m divided by λ_m , is that okay. So this is you can write it, you can take out 1 upon λ_m out, this is $g \phi_m$ and this is nothing but g_m , we are defining it like g_m , g_m by λ_m . So here is f_m , this is nothing but your f of m . So f_m which is a fourier coefficient of S with respect to ϕ_m , so f_m is given by g_m divided by λ_m .

(Refer Slide Time: 19:54)

The Fourier coefficients of the function $f(x)$ are related to the Fourier coefficients g_m of the function $g(x)$ by the relations

$$f_m = g_m / \lambda_m, \quad g_m = (g, \psi_m), \quad (14)$$

where λ_m are the eigenvalues of kernel K .

IT ROORKEE NITEL ONLINE CERTIFICATION COURSE 12

So here you can look at that, equation number 14 is valid in this way, that f_m is given by g_m divided by λ_m , is that okay. So using this now let us proceed to solve your Fredholm integral equation of 1st type we will try to solve for 2nd type and then we, if we have, we will discuss for 1st integral also. So let us try to solve, solution of a symmetric integral equation of non-homogeneous Fredholm integral equation. So please remember if it is homogeneous, then we already have solved, that is nothing but your eigenvalue Eigen function problem.

(Refer Slide Time: 21:14)

Solution of a Symmetric Integral Equation

Now we will use the Hilbert-Schmidt theorem to find the solution of the non-homogeneous Fredholm integral equation of the second kind

$$y(x) = f(x) + \lambda \int K(x,t)y(t)dt. \quad (15)$$

where $K(x,t)$ is a symmetric L_2 -kernel. Suppose λ is not an eigenvalue and $\lambda_1, \lambda_2, \dots$ are the eigenvalues of the kernel $K(x,t)$ and ψ_1, ψ_2, \dots are orthonormal system of eigenfunctions of the kernel $K(x,t)$. Using the Hilbert-Schmidt theorem, we have

$$y(x) - f(x) = \sum_{m=1}^{\infty} a_m \psi_m(x). \quad (16)$$

IT ROORKEE NITEL ONLINE CERTIFICATION COURSE 13

So now let us proceed for solving the non-homogeneous problem, that is y of x equal to f of x + λ $\int_a^b K(x,t)y(t)dt$. Here I am assuming that K is L_2 kernel, so that we can utilise the theory which we have discussed earlier. Okay. Now, we assume that this λ is not an

eigenvalue, we will consider the case when λ is an eigenvalue, but for the starting point let us assume that λ is not an eigenvalue. And we are able to solve the homogeneous problem, means we are able to find out all the eigenvalues corresponding to this symmetric kernel k .

So here we are assuming that $\lambda_1, \lambda_2, \dots$ all the eigenvalues of the kernel $k(x, t)$ and this ψ_1, ψ_2, \dots are orthonormal system of Eigen function of the kernel $k(x, t)$. So that we already have enquired. So theory says that you can always do it, okay. So now using the Hilbert Schmidt theorem, this $y(x) - \lambda f(x)$ is written as $\sum \lambda_m k(x, t) y(t) dt$. So now you can use Hilbert Schmidt theorem and say that $y(x) - \lambda f(x)$ can be expressed as this infinite series in terms of Eigen functions corresponding to this $k(x, t)$ which is uniformly, uniformly and absolutely convergent here.

(Refer Slide Time: 22:10)

where

$$\begin{aligned}
 a_m &= \int [y(x) - f(x)] \psi_m^*(x) dx \\
 &= \int y(x) \psi_m^*(x) dx - \int f(x) \psi_m^*(x) dx \\
 &= y_m - f_m(\text{say}), \tag{17}
 \end{aligned}$$

then using (14), we can write

$$a_m = \lambda y_m / \lambda_m. \tag{18}$$

Since λ is not an eigenvalue therefore using (17) and (18), we obtain

$$a_m = \frac{\lambda f_m}{\lambda_m - \lambda}, \quad y_m = \frac{\lambda_m f_m}{\lambda_m - \lambda}. \tag{19}$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 14

So this is by your Hilbert Schmidt result. And here we try to find out now this fourier coefficient that is a_m . So that, we know that a_m is basically what, a_m is nothing but $\int y(x) \psi_m^*(x) dx$.

(Refer Slide Time: 22:28)

$$y(x) = f(x) + \lambda \int_a^b K(x,t) y(t) dt$$

$$\frac{y(x) - f(x)}{\lambda} = \int_a^b K(x,t) y(t) dt$$

$$= \sum_m a_m \psi_m(x)$$

$$a_m = \int_a^b [y(x) - f(x)] \psi_m^*(x) dx$$

So here your inner product is defined like this, let me use, we already know this that y_m , y_x , y_x is equal to f of x + λ a to b k of x t y t dt , now you can take this out, so y x - f of x this side and it is λ a to b k of x t y t dt . And then using Hilbert Schmidt theorem, you can always write it like this as a_m and here we are assuming that ψ_m , $\psi_m^* x$ dx and how to find out this a_m , a_m is nothing but fourier coefficient corresponding to this y x - f of x . So that is y x - f of x and then $\int \psi_m^* x$ dx a to b .

(Refer Slide Time: 23:53)

The Fourier coefficients of the function $f(x)$ are related to the Fourier coefficients g_m of the function $g(x)$ by the relations

$$f_m = g_m / \lambda_m, \quad g_m = (g, \psi_m), \quad (14)$$

where λ_m are the eigenvalues of kernel K .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 12

So if you calculate this, this is what, this you can write it, you just take it, you separate these 2 integral. So y x $\psi_m^* x$ dx - f x , $\psi_m^* x$ dx , so where ψ_m^* is complex conjugate of ψ_m . But if you look at your previous thing, that your fourier coefficient corresponding

to your function f of x can be written as fourier coefficient of the unknown function, given function g as this f_m equal to g_m by λ . So here, in analogous manner you can say that a_m which is a fourier coefficient of $y - f$ can be written as, sorry can be written as fourier corresponding, fourier coefficient corresponding to this y .

(Refer Slide Time: 24:41)

The whiteboard contains the following handwritten equations:

$$y(x) = f(x) + \lambda \int_a^b K(x,t) y(t) dt$$

$$\frac{y(x) - f(x)}{\lambda} = \int_a^b K(x,t) y(t) dt$$

$$= \sum_m a_m \psi_m(x)$$

$$a_m = \int_a^b [y(x) - f(x)] \psi_m^*(x) dx$$

$$a_m = y_m - f_m = \frac{\lambda y_m}{\lambda}$$

$$y_m \left(1 - \frac{\lambda}{\lambda_m}\right) = f_m$$

So I can write it here a_m as λy_m divided by λ , so you can equate these 2 things. So when you equate these 2 things, you can get your a_m and y_m . So a_m is the fourier coefficients here and it is written as λy_m divided by λ , this is very easy, I can say that here we have a_m as $y_m - f_m$ and this is coming out to be λy_m upon λ . So if you will compare you will get y as $1 - \lambda$ upon λ is equal to f of m . So you can get, once your y_m is calculated, then you can calculate your a_m also.

Solution of a Symmetric Integral Equation

Now we will use the Hilbert-Schmidt theorem to find the solution of the non-homogeneous Fredholm integral equation of the second kind

$$y(x) = f(x) + \lambda \int K(x, t)y(t)dt. \quad (15)$$

where $K(x, t)$ is a symmetric L_2 -kernel. Suppose λ is not an eigenvalue and $\lambda_1, \lambda_2, \dots$ are the eigenvalues of the kernel $K(x, t)$ and ψ_1, ψ_2, \dots are orthonormal system of eigenfunctions of the kernel $K(x, t)$. Using the Hilbert-Schmidt theorem, we have

$$y(x) - f(x) = \sum_{m=1}^{\infty} a_m \psi_m(x). \quad (16)$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

So here you can get a_m as λf_m upon $\lambda_m - \lambda$, y equal to this. Okay, fine, so this is something we want to find out, y_m , okay. So now I can write it, $y(x)$ as what, so y , since, look at here, equation number 16, so $y(x) - f(x)$ is equal to, n equal to, this summation m equal to 1 to infinity a_m . a_m you have already obtained and ψ_m is already known to you, so you can get $y(x)$ in terms of $f(x) +$ this infinite series. So you can write it here, $y(x)$ equal to $f(x) + \lambda$, I am writing the value of a_m . So value of a_m is λf_m upon $\lambda_m - \lambda$.

(Refer Slide Time: 25:35)

Substituting this value of a_m in (16), we obtain the solution of the integral equation (15) in the form of an absolutely and uniformly convergent series

$$y(x) = f(x) + \lambda \sum_{m=1}^{\infty} \frac{f_m}{\lambda_m - \lambda} \psi_m(x)$$

or $= f(x) + \lambda \sum_{m=1}^{\infty} \int \frac{\psi_m(x)\psi_m^*(t)}{\lambda_m - \lambda} f(t)dt$

where the resolvent kernel is given by

$$\Gamma(x, t; \lambda) = \sum_{m=1}^{\infty} \frac{\psi_m(x)\psi_m^*(t)}{\lambda_m - \lambda}.$$

Here we note that, the singular points of the resolvent kernel Γ corresponding to a symmetric L_2 -kernel are simple poles and every pole is an eigenvalue of the kernel.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 15

So I can write it here, λf_m , λf_m upon $\lambda_m - \lambda$ $\psi_m(x)$. Now here you can utilise the value of f_m , f_m is what, f_m is the fourier coefficient of f , which is nothing but this a to b , I am not writing the limit because your interval maybe anything. So here f_m is

basically what, $\int_a^b \psi_m^*(x) \psi_m(t) dt$. So using the expression for f of m and I am using t as the integrable variable because we are already having x . So here $\int_a^b \psi_m^*(x) \psi_m(t) dt$ I am writing as $\int_a^b \psi_m^*(x) \psi_m(t) dt$.

So when you write it here, and we already know that this series is absolutely and uniformly convergent, so we can always interchange the integral sign and summation sign. So we can write it like this, $f(x) + \lambda \sum_{m=1}^{\infty} \int_a^b \psi_m^*(x) \psi_m(t) f(t) dt$. Now if we denote this $\sum_{m=1}^{\infty} \int_a^b \psi_m^*(x) \psi_m(t) dt$ as $\Gamma(x, t; \lambda)$ or you can say that if we denote this $\sum_{m=1}^{\infty} \int_a^b \psi_m^*(x) \psi_m(t) dt$ as $\Gamma(x, t; \lambda)$ and say that it is resolvent kernel, then your solution, it can be written as this.

(Refer Slide Time: 26:59)

The image shows three equations written on a whiteboard:

$$y(x) = f(x) + \lambda \int_a^b K(x, t) y(t) dt$$

$$y(x) = f(x) + \lambda \int_a^b \Gamma(x, t; \lambda) f(t) dt$$

$$\Gamma(x, t; \lambda) = \sum_{m=1}^{\infty} \frac{\psi_m^*(x) \psi_m(t)}{\lambda_m - \lambda}$$

So here your solution is given as y of x is equal to f of x + your λ times $\int_a^b \Gamma(x, t; \lambda) f(t) dt$ where $\Gamma(x, t; \lambda)$ is given as this infinite series $\sum_{m=1}^{\infty} \frac{\psi_m^*(x) \psi_m(t)}{\lambda_m - \lambda}$, sorry, $\psi_m^*(x)$, $\psi_m^*(x)$ $\psi_m^*(t)$ divided by $\lambda_m - \lambda$, okay. And this series is absolutely and uniformly convergent. Okay. So here solution is given by this. Now if you look at here, your λ , choice of λ is very very important because if λ is one of the Eigen value, then there is $\Gamma(x, t; \lambda)$ will not exist.

So here I am assuming that the singular point of this resolvent kernel is the values of λ which is equal to λ_m or you can say that the singular point of the resolvent kernel Γ corresponding to a symmetric L^2 kernel are simple poles because at the simple pole every pole is an Eigen values of the kernel. Or you can say that for λ equal to eigenvalues is your the singular point of this kernel Γ , resolvent kernel $\Gamma(x, t; \lambda)$

lambda. So using this, now let us try to apply the result for, actually solving the Fredholm integral equation of the 2nd kind, okay. So that we are going to do it in the next lecture, thank you very much.
