**Variational problems in Parametric form**

Consider the functional

$$I(x(t), y(t)) = \int_{t_0}^{t_1} F(t, x, y, \dot{x}, \dot{y}) dt, \quad \dots(1)$$

where  $x = \phi(t)$  and  $y = \psi(t)$ , for  $t_0 \leq t \leq t_1$ .

In order that the values of the functional depend only on the line, and not on the parametrization, it is both necessary and sufficient that the integrand in (1) does not contain  $t$  explicitly and that it is homogeneous of the first degree in  $\dot{x}$  and  $\dot{y}$ .

Hello Friends! Welcome to my lecture on Variational Problems in the Parametric form. Sometimes it is convenient advisable to ((00:27)) the variational problem to consider the Variational Problems in the Parametric form. In the Parametric form what we have is we have the functional eye where  $x$  is depending on  $x$  and  $y$  where  $x$  and  $y$  are functions of the parameter  $t$  and the integral is from  $t_0$  to  $t_1$   $\int_{t_0}^{t_1} f(t) x y x \dot{y} \dot{y} dt$  where  $x$  is a function of  $t$  and  $y$  is a function of  $t$   $x$  is given by  $\phi(t)$   $y$  is given by  $\psi(t)$  for  $t_0 \leq t \leq t_1$ .

Now in order that the values of the functional depend only on the line and not on the parameterization it is necessary and sufficient that the integrand in one does not contain  $t$  explicitly and that is that it is homogeneous in the first degree in  $x \dot{y}$  and  $y \dot{x}$ . Now what do you mean by the homogeneity in the first degree the first degree in  $x \dot{y}$  and  $y \dot{x}$ , here is the definition.

(Refer Slide Time: 01:26)

Thus

$$F(x, y, k\dot{x}, k\dot{y}) = kF(x, y, \dot{x}, \dot{y}), \quad k > 0. \quad \dots(2)$$

For example

$$I(x(t), y(t)) = \int_{t_0}^{t_1} \phi(x(t), y(t), \dot{x}(t), \dot{y}(t)) dt,$$

where  $\phi$  satisfies the homogeneity condition (2). Let us now consider a new parametric representation

$$\tau = \zeta(t) (\zeta'(t) \neq 0), \quad x = x(\tau), \quad y = y(\tau).$$

IT ROOBBEE NPTEL ONLINE CERTIFICATION COURSE 3

So the function  $f$  will be called homogenous of first degree in the variables  $x$  dot  $y$  dot if  $f(x) y k (x \text{ dot } y \text{ dot}), k (x \text{ dot}) k (y \text{ dot})$  gives you  $k$  times  $f(x)$  by  $x \text{ dot } y \text{ dot}$ . So here you can see in the functional not occur explicitly and then when we replace  $x \text{ dot } y k(x \text{ dot}) y \text{ dot}$  by  $k (y \text{ dot})$  then what we get is  $k$  times  $f(xy) x \text{ dot } y \text{ dot}$ .

So we will call  $f$  to be homogenous function of the first degree in  $x$  dot and  $y$  dot. For example if you consider the functional the variational problem  $\int_{t_0}^{t_1} \phi(x(t), y(t), \dot{x}(t), \dot{y}(t)) dt$  where  $\phi$  satisfies the homogeneity condition this one

(Refer Slide Time: 02:30)

Then the we  
it does not  
that means  
of this  
it become  
variants. So  
indo

Thus

$$F(x, y, k\dot{x}, k\dot{y}) = kF(x, y, \dot{x}, \dot{y}), \quad k > 0. \quad \dots(2)$$

For example

$$I(x(t), y(t)) = \int_{t_0}^{t_1} \phi(x(t), y(t), \dot{x}(t), \dot{y}(t)) dt,$$

where  $\phi$  satisfies the homogeneity condition (2). Let us now consider a new parametric representation

$$\tau = \zeta(t) (\zeta'(t) \neq 0), \quad x = x(\tau), \quad y = y(\tau).$$

IT ROOBBEE NPTEL ONLINE CERTIFICATION COURSE 3

let us show that  
depend on the  
parameterization  
if we do another  
parameterization  
problem then the  
remains in  
if let us consider  
parametric

representation say (zeta), Tau is equal to zeta (t) where zeta dot t is not equal to 0 and x is a function of Tau y is a function of Tau, so Tau is another

(Refer Slide Time: 03:00)

And the what we will see is that the integral t 0 to t 1 (phi x(t), y(t) x dot t y dot t dt ) can be written as tau 0 to tau 1 phi x (tau) y (tau) and x dot t will be equal to x dot t is dx by dt, x dot is equal to dx by dt since x is a function of tau x is a function of tau what we have written further x is equal to x (tau). So this is equal to dx over d tau into d tau y dt. And so we can write it as x dot tau into tau dot.

(Refer Slide Time: 03:35)

Thus

$$F(x, y, k\dot{x}, k\dot{y}) = kF(x, y, \dot{x}, \dot{y}), \quad k > 0. \quad \dots(2)$$

For example

$$I(x(t), y(t)) = \int_{t_0}^{t_1} \phi(x(t), y(t), \dot{x}(t), \dot{y}(t)) dt,$$

where  $\phi$  satisfies the homogeneity condition (2). Let us now consider a new parametric representation

$$\tau = \zeta(t) (\zeta'(t) \neq 0), \quad x = x(\tau), \quad y = y(\tau).$$

At the bottom of the slide, there are logos for IIT KOOBEE and NPTEL ONLINE CERTIFICATION COURSE, and a page number 3.

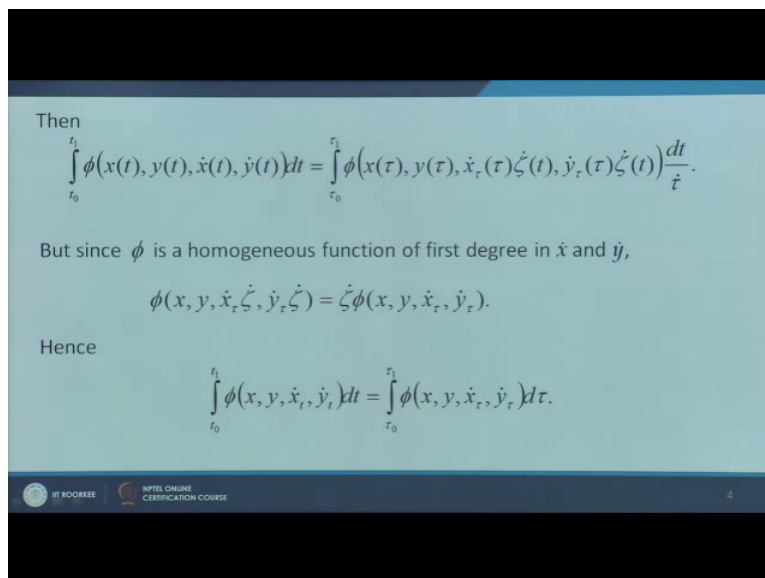

So what we will have here is that  $x(\tau) \dot{\tau} x(\tau) \dot{\tau} x(\tau) \dot{\tau}$  into  $\zeta \dot{t}$  because  $\tau$  is equal to  $t$  we have taken  $\tau$  equal to  $\zeta$   $t$   $\tau$  equal to  $\zeta$   $t$ .

(Refer Slide Time: 03:56)

So  $\tau \dot{\tau}$  will be  $\zeta \dot{t}$   $\zeta \tau$  over  $d \zeta$  over  $dt$  equal to  $\zeta \dot{t}$ . So this is nothing but  $\tau \dot{\tau}$  is equal to  $x \tau \dot{\tau}$  into  $\zeta \dot{t}$ .

(Refer Slide Time: 04:18)

So we will have here  $x(\tau) \dot{\tau}$  into  $\zeta \dot{t}$  into  $(\tau)$  (04:21)  $y \dot{t}$  is  $dy$  over  $dt$  which will be  $dy$  over  $d \tau$  into  $d \tau$   $y \dot{t}$  so will write it as  $y \tau \dot{\tau}$  into  $\zeta \dot{t}$  and again what we have here you can see  $\tau$  is equal to  $\zeta$   $t$   $\tau$  equal to  $\zeta$   $t$ , so  $d \tau$  equal to  $d \tau$   $\dot{t}$  into  $dt$   $d \tau$  equal to  $d$ .

So  $dt$  will be replaced by  $d\tau$  over  $d\tau$  over  $\tau$  dot. So  $\zeta$  dot is nothing but  $\tau$  dot. So we will have here  $\tau$  dot so now then we will have so this, this is same as this and since  $\phi$  is a homogeneous function of the first degree in  $x$  dot  $y$  dot. So  $\phi(x, y)$  by  $x \tau$  dot  $y \tau$  dot into  $\zeta$  dot comma  $y$  dot  $y \tau$  dot  $\tau$  dot into  $\zeta$  dot is equal to this  $\zeta$  dot times  $\phi(x, y)$  by  $x \tau$  dot  $y \tau$  dot because this  $\tau$  dot this  $\zeta$  dot  $x$  acts as a scalar  $k$ .

So this is of the form  $\phi(x, y)$  by  $k x \tau$  dot and then  $k y \tau$  dot. So this will be  $k$  times  $\phi(x, y)$  by  $x \tau$  dot  $y \tau$  dot. So you can replace this value here when we replace this value here then what will happen this  $\zeta$  dot will cancel with  $\tau$  dot because  $\tau$  dot and  $\zeta$  dot are same. So we shall have integral  $x_0$  to  $t_0$  to  $t_1$   $\phi(x, y)$  by  $x \tau$  dot  $y \tau$  dot  $\tau$  dot your this  $x$  dot  $t$  is same as  $x \tau$  dot and  $y$  dot  $t$  is we have written as  $y \tau$  dot.

So this is equal to integral  $\tau_0$  to  $\tau_1$   $\phi(x, y)$  by  $x \tau$  dot  $y \tau$  dot  $d\tau$ . This  $\tau$  as a suffix and  $t$  as a suffix we have added to show that this is the derivative with respect to  $t$  and this is the derivative with respect to  $\tau$ . Now you can see here that when  $\phi$  is a homogeneous function of the first degree in  $x$  dot and  $y$  dot then this is of the functionality independent of the parameterization. So the integrand remains unchanged with the change in the parametric representation.

(Refer Slide Time: 06:50)

Now for example you can consider let us say we know that the arc line from along the line from  $t_0$  to  $t_1$  if you take the curve any curve say this point corresponding to  $t_0$  the point corresponding to  $t_1$  and then the arc lines we know is under root  $dx$  square plus  $dy$  square

within the parametric form I can write it as if the curve is given as  $x$  equal to  $x(t)$   $y$  equal to  $y(t)$  where  $t$  varies from  $t_0$  to  $t_1$ .

Then  $dx$  is under root  $dx$  square plus  $dy$  square which we can write as  $dx$  by  $dt$  whole square  $dy$  by  $dt$  whole square into  $dt$ . So the length of the curve from  $t_0$  to  $t_1$  ok the arc length equal to arc length  $ab$  is equal to  $t_0$  to  $t_1$   $ds$  that is under root  $x$  dot square plus  $y$  dot square into  $dt$  where  $x$  dot  $y$  dot are derivatives with respect to derivatives of  $x$  and  $y$  with respect to  $t$ .

(Refer Slide Time: 08:24)

Now here you can see  $\phi(x, y, \dot{x}, \dot{y})$  is equal to square root  $x$  dot square plus  $y$  dot square. So this is homogeneous degree function in  $x$  dot  $y$  dot because when we replace  $x$  dot  $y$  dot by  $k$   $x$  dot  $k$   $y$  dot this is  $k$  this is also  $k$  so then this is equal to under root  $k$   $x$  dot square plus  $k$   $y$  dot square is equal to  $k$  times under root  $x$  dot square plus  $y$  dot square.

So this is equal to  $k$  times  $\phi(x, y, \dot{x}, \dot{y})$  So  $\phi$  is a homogeneous function of degree 1 in  $x$  dot and  $y$  dot similarly the area bounded by certain curve if you find the area bounded by certain curve then area is given by  $\frac{1}{2}$  integral from  $t_0$  to  $t_1$   $x$   $y$  dot minus  $y$   $x$  dot  $dt$ . So this is also here what we have  $\phi(x, y, \dot{x}, \dot{y})$  is equal to  $\frac{1}{2} x$   $y$  dot minus  $y$   $x$  dot.

So this implies  $\phi(x, y, k\dot{x}, k\dot{y})$  equal to you can replace  $x$  dot by  $k$   $x$  dot  $y$  dot by  $k$   $y$  dot and you see that it is  $k$  times  $\phi(x, y, \dot{x}, \dot{y})$  by so these are functional where the integrant  $\phi(x, y, \dot{x}, \dot{y})$  is a homogeneous function of degree 1 in  $x$  dot and  $y$  dot. So the examples of the functional we are actually interested in.

(Refer Slide Time: 10:42)

In order to find the extremals of the functionals of this kind,

$$I[x(t), y(t)] = \int_{t_1}^{t_2} \phi(x, y, \dot{x}, \dot{y}) dt,$$

where  $\phi$  is a homogeneous function of the first degree in  $x$  and  $y$ , and also for functionals with an arbitrary function  $\phi(t, x, y, \dot{x}, \dot{y})$ , we have to solve a system of Euler's equations

$$\phi_x - \frac{d}{dt} \phi_{\dot{x}} = 0 \quad \text{and} \quad \phi_y - \frac{d}{dt} \phi_{\dot{y}} = 0. \quad \dots (3)$$

INTEL ONLINE CERTIFICATION COURSE 6

Now say in order to find the extremals of functional of the form where phi does not contain t explicitly and it is a homogeneous function of a degree 1 in x dot and y dot. We what we do is we get the system of Euler's equation to find the extremum of this functional or extremals of the functional of this form we have the system of Euler's equation because x and y are the dependant variable t is the independent variable.

So  $\phi_x - \frac{d}{dt} \phi_{\dot{x}} = 0$  and  $\phi_y - \frac{d}{dt} \phi_{\dot{y}} = 0$ . But here what happens is that because t does not occur explicitly and x dot and y dot  $\phi(x, y, \dot{x}, \dot{y})$  is a homogeneous function of degree 1 in x dot and y dot. The two Euler's equations are not independent of each other.

While if while in the case where we have  $\phi(t, x, y, \dot{x}, \dot{y})$  and t is independent variable x and y are dependent variables then we have these two equations as independent of each other and we solve them according to the example which we have done earlier where we had discussed the variational problem in case where we have more than one dependent variable.

So (ther) we can solve the problem there, here these two equations are not independent of each other. So to find the external we must consider one of the Euler's equation and integrated together with the equation defining with the choice of the parameter.

(Refer Slide Time: 12:23)

To find the extremals, we must consider one of the Euler equation (3) and integrate it together with the equation defining the choice of parameter.

For example, to the equation  $\phi_x - \frac{d\phi_x}{dt} = 0$  we can adjoin the equation  $\dot{x}^2 + \dot{y}^2 = 1$  which indicates that the arc length of the curve is taken as parameter.

INTEL ONLINE CERTIFICATION COURSE 7

Now for example we have the equation  $\phi(x) - \frac{d}{dt} \phi(\dot{x}) = 0$  ok. So for example we will solve one of the two Euler's equation say for example  $\phi(x) - \frac{d}{dt} \phi(\dot{x}) = 0$ . And together with the equation  $\dot{x}^2 + \dot{y}^2 = 1$  which indicates that the arc lines of the curve is taken as a parameter.

(Refer Slide Time: 12:50)

The Weierstrass form of Euler's equations (3)

$$\frac{1}{\rho} = \frac{\phi_{xy} - \phi_{yx}}{\phi_1 (\dot{x}^2 + \dot{y}^2)^{3/2}}$$

where  $\rho$  is the radius of curvature of the extremal and  $\phi_1$  is the common value of the ratios

$$\phi_1 = \frac{\phi_{xx}}{\dot{y}^2} = \frac{\phi_{yy}}{\dot{x}^2} = -\frac{\phi_{xy}}{\dot{x}\dot{y}}$$

INTEL ONLINE CERTIFICATION COURSE 8

Now to solve this equation we will need the Weierstrass form of Euler's equation which is  $\frac{1}{\rho} = \frac{\phi_{xy} - \phi_{yx}}{\phi_1 (\dot{x}^2 + \dot{y}^2)^{3/2}}$  where  $\rho$  is the radius curvature of the external and  $\phi_1$  is the common value of the ratios.

So  $\Phi_1$  is given by  $\phi(x, y, \dot{x}, \dot{y}) = \frac{1}{2}(\dot{x}^2 + \dot{y}^2) - a^2(x\dot{y} - y\dot{x})$ . This is the Weierstrass form of the Euler's Equation we can solve a Euler's equation by using this Weierstrass form also.

(Refer Slide Time: 13:30)

Say for consider this the external 0 to t 1(x dot square) plus a minus y x is (real) Now in this

**Example 1.** Find the extremal of

$$I[x(t), y(t)] = \int_{t_0}^{t_1} [(\dot{x}^2 + \dot{y}^2)^{1/2} + a^2(x\dot{y} - y\dot{x})] dt$$

**Solution:** In this problem, the integrand  $\phi(x, y, \dot{x}, \dot{y})$ , is a homogeneous of degree one.

We have

$$F_{\dot{x}\dot{x}} = a^2, \quad F_{\dot{y}\dot{y}} = -a^2, \quad F_1 = \frac{1}{(\dot{x}^2 + \dot{y}^2)^{3/2}},$$

hence Weierstrass form of Euler equations  $\Rightarrow$

IT ROOBBEE NPTEL ONLINE CERTIFICATION COURSE

example let us equation; find of  $I[x(t), y(t)] = \int_0^1 (\dot{x}^2 + \dot{y}^2)^{1/2} + a^2(x\dot{y} - y\dot{x}) dt$  where a some constant. the

integrand  $\phi(x, y, \dot{x}, \dot{y})$  is a homogeneous function of degree 1 in  $\dot{x}, \dot{y}$ .

(Refer Slide Time: 14:00)

So let us see  $\phi(x, y, \dot{x}, \dot{y}) = (\dot{x}^2 + \dot{y}^2)^{1/2} + a^2(x\dot{y} - y\dot{x})$  equal to  $(k^2\dot{x}^2 + k^2\dot{y}^2)^{1/2} + a^2(kx\dot{y} - ky\dot{x})$  plus a you can see  $x\dot{y}$  by  $kx\dot{y}$  then

$$\begin{aligned} \phi(x, y, \dot{x}, \dot{y}) &= (\dot{x}^2 + \dot{y}^2)^{1/2} + a^2(x\dot{y} - y\dot{x}) \\ \phi(kx, ky, k\dot{x}, k\dot{y}) &= (k^2\dot{x}^2 + k^2\dot{y}^2)^{1/2} + a^2(kx\dot{y} - ky\dot{x}) \\ &= k \{ (\dot{x}^2 + \dot{y}^2)^{1/2} + a^2(x\dot{y} - y\dot{x}) \} \\ &= k \phi(x, y, \dot{x}, \dot{y}) \end{aligned}$$

you can replace  $\dot{x}, \dot{y}$  is  $\dot{x}^2 + \dot{y}^2$  to the power half square times  $(x\dot{y} - y\dot{x})$ . Now when we replace  $\dot{x}$  and  $\dot{y}$  by what we get is  $k$

$(\dot{x}^2 + \dot{y}^2)^{1/2} + a^2(x\dot{y} - y\dot{x})$  raise to the power half plus a square  $(kx\dot{y} - ky\dot{x})$  which is equal to  $k$  times  $(\dot{x}^2 + \dot{y}^2)^{1/2} + a^2(x\dot{y} - y\dot{x})$  raise to the power half plus a square times  $(x\dot{y} - y\dot{x})$  which is equal to  $k$  times  $(\phi(x, y, \dot{x}, \dot{y}))$ .

(Refer Slide Time: 15:15)

The image shows handwritten mathematical work on a whiteboard. On the left, it shows the partial derivatives of a function  $\phi$  with respect to  $x$  and  $y$ , resulting in  $-a^2x$  and  $-a^2y$  respectively. In the center, the function  $\phi(x, y, z, t) = (x^2 + y^2)^{1/2} + a^2(xy - xz)$  is defined, and its partial derivatives are calculated, leading to  $F_x = a^2y$  and  $F_y = a^2x$ . On the right, the partial derivatives of  $\phi$  with respect to  $x$  and  $y$  are shown again, resulting in  $F_x = \frac{F_x x}{y^2}$  and  $F_y = \frac{F_y y}{x^2}$ .

So it is a homogeneous function of degree 1 in  $x$  dot  $y$  dot. Now you can see here that if you instead of phi you write it denote it by  $f$ , ok.

So in this solution we have actually denoted phi by  $f$ . So if you write  $f(x, y)$  instead of phi you write it as  $(x^2 + y^2)^{1/2} + a^2(xy - xz)$  then you can see that if you replace if you write it as  $f(x, y)$  then you differentiate with respect to  $x$  partially with respect to  $x$  what you get is a square ( $y$  dot) and when you differentiate with respect to  $y$  dot again you get  $\Delta^2 f$  by  $\Delta x \Delta y$  dot which is equal to a square.

So this is this implies  $f(x, y)$  equal to a square. Similarly if you differentiate  $f$  with respect to  $y$  what we will get is with respect to  $y$  minus a square  $x$  dot and when we differentiate it with respect to  $x$  dot further we will get minus a square so we can say that this is  $f$  by  $x$  dot. Now in order to find  $f_1$   $f_1$  means  $\phi_1$ , so  $\phi_1$  is  $\phi(x, y)$  over  $y$  dot square.

So  $f_1$  is equal to  $f(x, y)$  over  $y$  dot square. So let us find  $f(x, y)$ , so first we find  $f(x, y)$  over  $y$  dot square is equal to  $\frac{1}{2}(x^2 + y^2)^{-1/2} + a^2x$  and then we have minus a square  $y$  when we differentiate with respect to  $x$  dot. So this 2 will cancel and we get  $x$  dot square plus  $y$  dot square raise to the power minus half into  $x$  dot minus a square  $y$ .

Now let us differentiate this further with respect to  $x$  dot again. So  $f(x, y)$  over  $y$  dot square here we have a product of two functions each containing  $x$  dot so we have to use that formula for product of derivative of the product so minus 1 by 2  $(x^2 + y^2)^{-3/2} \cdot 2x$  plus  $y$  dot square raise to the power

minus 3 by 2 into 2 x dot into x dot. So 2 times x dot square x dot square and then this is minus a square sorry this is further we have x dot square plus y dot square raise to the power half into derivative of x dot is 1. And derivative of minus a square y with respect to x dot is 0. So this f( x dot x dot).

(Refer Slide Time: 18:58)

We can simplify it we can write it as here it is minus half. So we can write it as x dot square plus y dot square raise to the power minus half and here we will have minus x square plus y dash ok 1 upon x dot square plus y dot square minus x dot square plus 1.

So this is x dot square plus y dot square minus x dot square so we get y dot square divided by x dot square plus y dot square divided by to the power 3 by 2. So f(x dot is this and for phi 1 ok therefore (phi 1) therefore hence f 1, f 1 is equal to y dot x square upon (x dot) square plus (y dot) square to the power 3 by 2 f(x dot x dot) divided by (y dot) square. So 1 upon so this will cancel.

And we will get f 1 ok f 1 is 1 upon (x dot) square plus (y dot) square to the power 3 by 2. Now let us use Weierstrass form of Euler's equation. So we go to the Weierstrass form of Euler's equation so 1 by Rho, 1 by Rho equal to phi(x) y dot minus phi ( x dot y ) divided by phi dot 1 (x dot) square plus (y dot) square to the power 3 by 2. Now in place of phi we are writing f here.

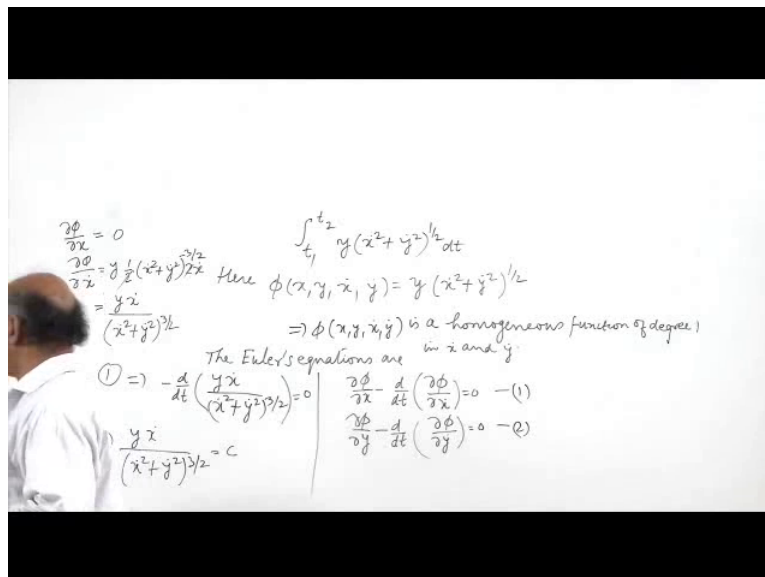

So we have 1 by Rho f(x y dot ) minus f( x dot y) divided by f 1 x dot square plus y dot square to the power 3 by 2. And this is equal to, this is equal to f(x y dot) f x ok f( x y dot) we

have find  $f(x, \dot{x}, \dot{y})$  came out to be we had found  $f(x, \dot{x}, \dot{y})$ ,  $f(x, \dot{x}, \dot{y})$  is equal to a square. So we have a square minus and this is (minus a square).

And then we have  $f(1)$  into  $x \dot{x}^2 + y \dot{y}^2$  to the power  $3/2$  equal to 1. So we get  $1$  by  $Rho$  is equal to  $2a^2$  or  $Rho$  equal to  $1/2 a^2$ . Now here  $Rho$  is the radius of curvature, so radius of curvature is a constant quantity and therefore the extremals are circles. So this  $Rho$  this  $Rho$  is the radius of curvature,.

So we have the radius of curvature of the extremal, the radius of curvature of the extremal is a constant. And therefore the extremal is a (circ) so extremal because the radius of curvature of circle is a constant quantity. Now it is the radius now what we have is . Let us now so the extremals are circles now find the extremal of this problem.

(Refer Slide Time: 23:45)

Let us see this problem. So we have integral over  $t_0$  to  $t_1$ ,  $t_1$  to  $t_2$   $y$  times  $(x \dot{x}^2 + y \dot{y}^2)$  to the power half  $dt$ . So here  $\phi(x, y, \dot{x}, \dot{y})$  is equal to  $y$  times  $(x \dot{x}^2 + y \dot{y}^2)$  raise to the power half.

And therefore we can (ans) moreover we notice that when we replace  $x \dot{x}$  by  $k x \dot{x}$  and  $y \dot{y}$  by  $k y \dot{y}$  then what we get is  $y$  times  $(k x \dot{x})^2 + (k y \dot{y})^2$  to the power half. So this will give you  $k y$  into  $x \dot{x}^2 + y \dot{y}^2$  to the power half. So  $\phi$  is a homogeneous function of degree 1 in  $x \dot{x}$  and  $y \dot{y}$  ok.

Now so the euler's equations are  $\frac{\partial \phi}{\partial x} - \frac{d}{dt} \left( \frac{\partial \phi}{\partial \dot{x}} \right) = 0$  and  $\frac{\partial \phi}{\partial y} - \frac{d}{dt} \left( \frac{\partial \phi}{\partial \dot{y}} \right) = 0$  we have here  $x$  and  $y$  are dependant variables ( $t$  is)  $\frac{\partial \phi}{\partial x} - \frac{d}{dt} \left( \frac{\partial \phi}{\partial \dot{x}} \right) = 0$  and  $\frac{\partial \phi}{\partial y} - \frac{d}{dt} \left( \frac{\partial \phi}{\partial \dot{y}} \right) = 0$

$\dot{x}$  equal to 0, and  $\frac{\delta \phi}{\delta y} - \frac{d}{dt} \frac{\delta \phi}{\delta \dot{y}}$  equal to 0. Now we will pick up one equation from the here and find the extremals of the given problem.

And then we show that the second equation is not independent on the first equation we solve second equation there also we will get the same extremals. So let us see how we will pick the first equation. So let us take the first equation here  $\frac{\delta \phi}{\delta x}$  if we find  $\frac{\delta \phi}{\delta x}$  what we will get 0 here. And if we find  $\frac{\delta \phi}{\delta \dot{x}}$  then what we will get  $y \cdot \frac{1}{2} \dot{x}^2 + \frac{1}{2} \dot{y}^2$  raise to the power minus  $\frac{3}{2}$  into  $2x \dot{x}$ .

So this 2 will cancel and will get  $y \dot{x}$  over  $\dot{x}^2 + \dot{y}^2$  to the power  $\frac{3}{2}$ . So this will give you 0 ok the first Euler's equation. The first Euler's equation gives us  $-\frac{d}{dt} \frac{\delta \phi}{\delta \dot{x}}$  by  $\frac{\delta \phi}{\delta x}$ , so  $y \dot{x}$  divided by  $\dot{x}^2 + \dot{y}^2$  raise to the power  $\frac{3}{2}$  equal to 0, ok because this is 0.

So now integrating with respect to  $t$  what we get  $y(\dot{x})$  divided by  $\dot{x}^2 + \dot{y}^2$  to the power  $\frac{3}{2}$  equal to some constant. Let us say  $c$  ok. Now there arise two possibilities. The possibilities are the constant  $c$  is 0 and the constant  $c$  is not 0. So let us discuss the two cases separately.

(Refer Slide Time: 27:58)

So we will let us consider the case 1  $c$  is equal to 0. The constant  $c$  is equal to 0 will give you  $y$  equal to 0 or  $x$  dot equal to 0. So when  $c$  is equal to 0 either  $y$  is 0 or  $x$  dot is 0. So  $x$  dot equal to 0 gives you  $x$  equal to some constant. You can say  $c = 1$ , ok so when  $c$  is equal to 0  $y$  equal to 0 could be extremal or  $x$  equal to a constant could be an extremal.

Now let us see the case 2 when  $c$  is not 0, when  $c$  is not 0 then we will get  $y x$  dot divided by  $x$  dot square plus  $y$  dot square raise to the power 3 by 2 equal to  $c$ . So we will get here  $y x$  dot ok  $y x$  dot upon  $x$  dot square plus  $y$  dot square to the power 3 by 2 we will get we had to solve it so we will get  $y$  square, ok it is to square it  $y$  square  $x$  dot square upon  $x$  dot square we have  $x$  dot square to the power  $\frac{\partial \phi}{\partial x\dot{}}$  it should be minus half not 3 by 2. It should be minus half here because?

(Refer Slide Time: 30:12)

$$\Rightarrow \frac{1}{r^2} = 2a^2,$$
 Therefore the extremals are circles  
**Example 2.** Find the extremal of  $\int_{t_1}^{t_2} y(\dot{x}^2 + \dot{y}^2)^{1/2} dt,$   
**Solution:** Here  $\phi(x, y, \dot{x}, \dot{y}) = y(\dot{x}^2 + \dot{y}^2)^{1/2} \dots(1)$   
 Showing that  $\phi(x, y, \dot{x}, \dot{y})$  is a homogeneous function of degree one.

We are differentiating phi with respect to x dot we are differentiating this is phi, phi y phi equal to y times x dot square plus y dash square to the power half when we differentiate with respect to x dot we get y times 1 by 2 x dot square plus y dot square to the power minus half into 2x dot. So x dot y upon x dot square plus y do square to the power half. So this is half here.

(Refer Slide Time: 30:32)

or  $\frac{c}{\sqrt{y^2+c^2}} dy = dx$   
 or  $\frac{dy}{\sqrt{y^2+c^2}} = \frac{1}{c} dx$   
 or  $\text{Cosh}^{-1} \frac{y}{c} = \frac{1}{c} x + \frac{1}{c_2}$   
 $y = c \text{Cosh} \left( \frac{x}{c} + \frac{1}{c_2} \right)$   
 Case I,  $C=0$   
 Then  $y=0$  or  $x=0 \Rightarrow x=c_1$   
 Case II, when  $c \neq 0$   
 $\frac{y \dot{x}}{(\dot{x}^2 + \dot{y}^2)^{1/2}} = c$   
 $\Rightarrow \frac{y^2 \dot{x}^2}{(\dot{x}^2 + \dot{y}^2)^2} = c^2$   
 $\frac{y^2}{c^2} = \frac{\dot{x}^2 + \dot{y}^2}{\dot{x}^2} = 1 + \left( \frac{\dot{y}}{\dot{x}} \right)^2$   
 $\frac{dy}{dx} = \frac{\sqrt{y^2 - c^2}}{c}$   
 The Euler's equations are  
 $\frac{\partial \phi}{\partial x} - \frac{d}{dt} \left( \frac{\partial \phi}{\partial \dot{x}} \right) = 0 \dots (1)$   
 $\frac{\partial \phi}{\partial y} - \frac{d}{dt} \left( \frac{\partial \phi}{\partial \dot{y}} \right) = 0 \dots (2)$

So we get y x dot upon x dot square plus y dot square to the power half and this will give you when we square this y square x dot square upon x dot square plus y dot square is equal to c square. So r we can say y square by c square equal to x dot square plus y dot square divided

by  $x \dot{\ }^2$  which is  $1 + y \dot{\ }^2$  upon  $x \dot{\ }^2$  whole square  $y \dot{\ }$  is  $dy$  by  $dt$   $x \dot{\ }$  is  $dx$  by  $dt$ . So  $y \dot{\ } / x \dot{\ }$  is  $1 + dy$  by  $dx$  whole square.

So  $1 + dy$  by  $dx$  whole square. So what we will get  $dy$  by  $dx$  equal to  $y^2$  minus  $c^2$  under root divided by  $c$  or we can say  $c$  upon under root  $y^2$  minus  $c^2$   $dy$  is equal to  $dx$ . So this will give you when we integrate this so we can say  $dy$  upon under root  $y^2$  minus  $c^2$  is equal to  $1/c \int dx$  ok.

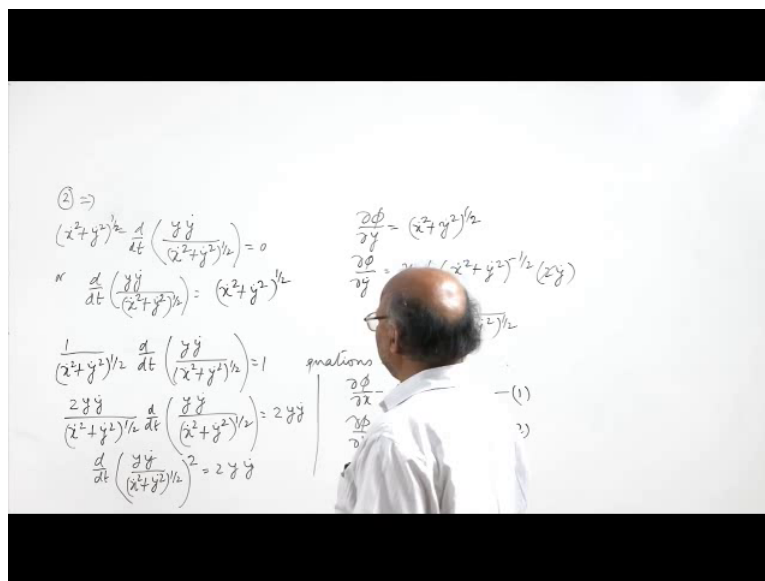

So this gives you when we integrate we get  $\cos$  hyperbolic inverse  $y/c$  equal to  $1/c$  into  $x$  plus  $1/c$  some constant  $c^3$  we can write or we have already taken  $c^1$  we have taken so let us write  $c^2$  here. So then what we will get  $y$  equal to  $c$  times  $\cos$  hyperbolic  $y$  (sorry)  $\cos$  hyperbolic  $x$   $y/c$  plus  $1/c^2$ . So one solution we had as  $y$  equal to  $0$  and over solution was  $x$  equal to  $c^1$  and this is the third solution  $y$  equal to  $c$  times  $\cos$  hyperbolic  $x$  by  $c$  plus  $1/c^2$ .

So there are 3 extremals of the given problem which we have found by solving the first Euler's equation. Let us show that the second Euler's equation when we solve it also gives us the same same extremals. So let us what we will do is when we will simplify this second Euler's equation we shall see that we get this equation  $y \dot{\ }^2$  upon  $x \dot{\ }^2$  plus  $y \dot{\ }^2$  square to the power half is equal to  $c$  which when we solve by taking the  $k/c$  equal to  $0$  and  $c^0$  equal to  $0$ , we are arrive at the 3 extremals  $y$  equal to  $0$   $x$  equal to  $c^1$  and  $y$  equal to  $c \cos$  hyperbolic  $x$  by  $c$  plus  $1/c^2$ .

So we shall simply prove that the second Euler's equation when simplified gives rise to the same equation this one and therefore when solved this equation gives us the same extremals. So let us solve the second Euler's equation.

(Refer Slide Time: 34:19)

So second Euler's equation we need to find  $\frac{\partial \phi}{\partial y}$  and  $\frac{\partial \phi}{\partial y}$ . If we find it is  $x \dot{x}^2 + y \dot{y}^2$  raised to the power half. And when we find partial derivative of  $\phi$  with respect to  $y \dot{y}$  what we will get  $y$  times  $1$  by  $2 x \dot{x}^2 + y \dot{y}^2$  raised to the power minus half into  $2 y \dot{y}$ . So this will cancel and we will get  $y \dot{y}$  divided by  $x \dot{x}^2 + y \dot{y}^2$  to the power half.

And therefore second Euler's equation gives us partial derivative with respect to  $y$  so  $1$  upon  $x \dot{x}^2 + y \dot{y}^2$  minus  $d$  over  $dt$  ( $y \dot{y}$  divided by  $x \dot{x}^2 + y \dot{y}^2$  to the power half) equal to  $0$ . We can write it in this form or  $d$  over  $dt$  ( $y \dot{y}$  upon  $x \dot{x}^2 + y \dot{y}^2$  to the power half) is equal to  $1$  by  $x \dot{x}^2 + y \dot{y}^2$ , no wait wait.

We have this  $(x \dot{x}^2 + y \dot{y}^2)^{1/2}$ ,  $(x \dot{x}^2 + y \dot{y}^2)$  to the power half so we get here  $(x \dot{x}^2 + y \dot{y}^2)^{1/2}$ . Now what we will do is this gives you  $1$  upon  $x \dot{x}^2 + y \dot{y}^2$  to the power half into  $d$  over  $dt$  ( $y \dot{y}$  upon  $x \dot{x}^2 + y \dot{y}^2$  raised to the power half) equal to  $1$ , ok.

Let us divide by  $x \dot{x}^2 + y \dot{y}^2$  to the power half then what we do is we multiply both sides by  $2 y \dot{y}$ . So  $2 y \dot{y}$  upon  $x \dot{x}^2 + y \dot{y}^2$  raised to the power half  $d$  over  $dt$  of  $(y \dot{y} / (x \dot{x}^2 + y \dot{y}^2)^{1/2})$  raised to the power half equal to  $2 y \dot{y}$ .

Now we can see that the left hand side is the differential of  $(x^2 + y^2)^{1/2}$ , when we differentiate  $y \dot{y}$  upon  $x \dot{x}^2 + y \dot{y}^2$  whole to the power half raise to the power half, what we get? 2 times  $y \dot{y}$  upon  $x \dot{x}^2 + y \dot{y}^2$  to the power half into the derivative of  $y \dot{y}$  upon  $x \dot{x}^2 + y \dot{y}^2$  to the power half.

(Refer Slide Time: 38:49)

The whiteboard shows the following derivations:

$$\begin{aligned} \textcircled{2} \Rightarrow & \frac{d}{dt} \left( \frac{y \dot{y}}{(x^2 + y^2)^{1/2}} \right) = 0 \\ \text{or } & \frac{d}{dt} \left( \frac{y \dot{y}}{(x^2 + y^2)^{1/2}} \right) = (x^2 + y^2)^{-1/2} \\ & \frac{1}{(x^2 + y^2)^{1/2}} \frac{d}{dt} \left( \frac{y \dot{y}}{(x^2 + y^2)^{1/2}} \right) = 1 \quad \text{equations are} \\ & \frac{2y \dot{y}}{(x^2 + y^2)^{3/2}} \frac{d}{dt} \left( \frac{y \dot{y}}{(x^2 + y^2)^{1/2}} \right) = 2y \dot{y} \quad \left. \begin{aligned} \frac{\partial \phi}{\partial x} - \frac{d}{dt} \left( \frac{\partial \phi}{\partial \dot{x}} \right) &= 0 \quad \text{---(1)} \\ \frac{\partial \phi}{\partial y} - \frac{d}{dt} \left( \frac{\partial \phi}{\partial \dot{y}} \right) &= 0 \quad \text{---(2)} \end{aligned} \right\} \\ & \frac{d}{dt} \left( \frac{y \dot{y}}{(x^2 + y^2)^{1/2}} \right)^2 = 2y \dot{y} \quad \left. \begin{aligned} \frac{y \dot{y}^2}{(x^2 + y^2)} - y \dot{y}^2 &= c^2 \\ \text{or } \frac{y \dot{y}^2}{x^2 + y^2} &= c^2 \\ \text{or } \frac{y \dot{x}}{\sqrt{x^2 + y^2}} &= c \end{aligned} \right\} \end{aligned}$$

So what we get is this also we can write in the following form,  $y \dot{y} \frac{d}{dt} (y \dot{y} \text{ over } x \dot{x}^2 + y \dot{y}^2)$  to the power half equal to  $\frac{d}{dt} (y \dot{y}^2)$ , ok. I will integrate both sides so  $y \dot{y}$  upon  $x \dot{x}^2 + y \dot{y}^2$  this to the power 2. So this square is equal to  $y \dot{y}^2$  that is right plus  $c^2$  constant we can take as  $c^2$ .

So what we will get  $y \dot{y}$  upon  $x \dot{x}^2 + y \dot{y}^2$  ok this is to the power half here. Let me write it again  $x \dot{x}^2 + y \dot{y}^2$  raise to the power half whole to the power 2. So what we will get  $y \dot{y}^2$  upon  $x \dot{x}^2 + y \dot{y}^2$  minus  $y \dot{y}^2$  equal to  $c^2$ .

So when we take LCM what we get  $y \dot{y}^2$  will cancel and we will get  $x \dot{x}^2$  equal to  $c^2$  or we will take the square root and we will have  $y \dot{x}$  upon square root  $x \dot{x}^2 + y \dot{y}^2$  equal to  $c$ . And this is what we wanted  $y \dot{x}$  upon  $x \dot{x}^2 + y \dot{y}^2$  to the power half is equal to  $c$ .

So second equation also leads us to the same equation which when we solve we get the extremals as we have got the extremals from the by solving the first equation. So the two equations are not independent we can solve any one equation and use the parametric form and the parametric relation and get the extremals.

So this is the second example on this variational form in our next lecture we shall consider the variational problems with moving boundaries. So far we have considered the variational problems where both the end points  $x_1, y_1, x_2, y_2$  were fixed now we shall take the variational problems where either one or both the end points are not fixed they are moving.

So that is, that will be discussed in the next lectures ok, thank you very much for your attention.
