 with respect

Integro differential equation
 A linear integro-differential equation is an equation of the form

$$a_0(x)y^{(n)}(x) + a_1(x)y^{(n-1)}(x) + \dots + a_n(x)y(x) + \sum_{m=0}^s \int_0^x K_m(x,t)y^{(m)}(t)dt = f(x) \quad \dots(1)$$

where $a_0(x), a_1(x), \dots, a_n(x), f(x), K_m(x,t)$ ($m = 0, 1, \dots, s$) are known functions and $y(x)$ is the unknown function.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

friends! I
 you to be lecture
 differential
 linear integral
 equation is an
 the form $a_0(x)$
 $y^{(n)}(x)$, $y^{(n-1)}(x)$ is the
 derivative of y
 to x plus $a_1(x)y^{(n-1)}$

$y^{(n-2)}(x)$ and so on $a_n(x)y(x)$ plus sigma s is equal to n equal to 0 to s 0 to x $k_m(x,t)y^{(m)}(t)dt$ is equal to $f(x)$ where $a_0, a_1, \dots, a_n(x)$, and $f(x), k_m(x,t)$ a m varying from 0 to x are known functions and $y(x)$ is the unknown function.

(Refer Slide Time: 01:02)

Further let,

$$y(0) = y_0, y'(0) = y'_0, \dots, y^{(n-1)}(0) = y_0^{(n-1)},$$

be the initial conditions.

Let the coefficients $a_k(x) = \text{constant} = a_k$ for $k = 0, 1, 2, \dots, n$ and let $K_m(x, t) = K_m(x - t)$, $m = 0, 1, 2, \dots, s$ i.e. all the K_m depend on the difference $x - t$ of arguments.

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE

Further we are given the conditions on y , $y(0)$ equal to y_0 , $y'(0)$ equal to y'_0 and so on $y^{(n-1)}(0)$ equal to $y_0^{(n-1)}$ these are the initial conditions.

(Refer Slide Time: 01:15)

Integro differential equation

A linear integro-differential equation is an equation of the form

$$a_0(x)y^{(n)}(x) + a_1(x)y^{(n-1)}(x) + \dots + a_n(x)y(x) + \sum_{m=0}^s \int_0^x K_m(x,t)y^{(m)}(t)dt = f(x), \quad \dots(1)$$

where $a_0(x), a_1(x), \dots, a_n(x), f(x), K_m(x,t)$ ($m = 0, 1, \dots, s$) are known functions and $y(x)$ is the unknown function.

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE

Let us assume that the coefficients $a_k(x)$ of the integro differential equation these coefficients $a_k(x)$ are constants let us denote the coefficients $a_k(x)$ by the constant a_k for k equal to 1, 2 and so on upto n . And let us assume that the kernel $K_m(x,t)$ kernel $K_m(x,t)$ is equal to $K_m(x - t)$ for value all values of m that is 0,1,2 and so on upto s .

That is all the k ms depends on the difference $(x \text{ minus } t)$ of arguments, without any loss of generality we can assume a_0 equal to 1 because if it is not 1 we can divide the equation by a_0 .

(Refer Slide Time: 01:59)

Without any loss of generality, let $a_0 = 1$ then equation (1) reduces to

$$y^{(n)}(x) + a_1 y^{(n-1)}(x) + \dots + a_n y(x) + \sum_{m=0}^s \int_0^x K_m(x-t) y^{(m)}(t) dt = f(x), \quad \dots(2)$$

a_1, a_2, \dots, a_n being constants.

Let the Laplace transform of $f(x)$ and $K_m(x)$ be $F(s)$ and $\bar{K}_m(s)$ ($m = 0, 1, 2, \dots, s$).

So when we assume a_0 equal to 1 then the equation 1 reduces to this form. So we have $y^{(n)}(x)$ n th derivative of y with respect to x plus a_1 (n minus 1) th derivative of y with respect to x and so on $a_n y(x)$ and then sigma a_m equal to 0 to s this integral equal to $f(x)$ a_1, a_2, a_n are constants.

(Refer Slide Time: 02:20)

$$F(s) = \int_0^\infty e^{-s x} f(x) dx$$

$$\bar{K}_m(s) = \int_0^\infty e^{-s x} K_m(x) dx, \quad m=0,1,2,\dots,s$$

$$Y(s) = \int_0^\infty e^{-s x} y(x) dx$$

Now let us assume that the Laplace transform of $f(x)$ is $f(s)$. So by definition of Laplace transform $f(s)$ is equal to $\int_0^{\infty} e^{-sx} f(x) dx$ and Laplace transform $a_m(x)$ we assume as $\bar{K}_m(s)$.

So $\bar{K}_m(s)$ is equal to $\int_0^{\infty} e^{-sx} a_m(x) dx$ where m is equal to $0, 1, 2$ and so on upto n . Further let us assume that the Laplace transform of the unknown function $y(x)$ be $Y(s)$. So we assume $Y(s)$ equal to $\int_0^{\infty} e^{-sx} y(x) dx$.

(Refer Slide Time: 03:18)

Without any loss of generality, let $a_0 = 1$ then equation (1) reduces to

$$y^{(n)}(x) + a_1 y^{(n-1)}(x) + \dots + a_n y(x) + \sum_{m=0}^{s-1} \int_0^x K_m(x-t) y^{(m)}(t) dt = f(x), \quad \dots(2)$$

a_1, a_2, \dots, a_n being constants.

Let the Laplace transform of $f(x)$ and $K_m(x)$ be $F(s)$ and $\bar{K}_m(s)$ ($m = 0, 1, 2, \dots, s-1$).

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE

Now what we do is, we take the Laplace transform of both sides of the equation 2 and they recall the formula for the Laplace transform of the n th derivative of $y(x)$.

(Refer Slide Time: 03:30)

So Laplace transform of n th derivative of y(x) is given by s to the power n Laplace transform of y(x) minus s n minus 1 y at (0) minus s n minus 2 y dash at (0) and so on minus y (n minus 1) at (0).

Now according to our hypothesis assumption this is s to the power n Laplace transform of y(x) is y(s) so we have y(s) minus s n minus 1 y(0) is y 0 minus s n minus 2 y 0 dash and so on minus y 0 (n minus 1).

(Refer Slide Time: 04:28)

Further, let the Laplace transform of $y(x)$ be $Y(s)$.
 Then, taking the Laplace transform of both sides of (2), we get

$$\begin{aligned} & [s^n Y(s) - s^{n-1}y_0 - s^{n-2}y'_0 - \dots - y_0^{(n-1)}] \\ & + a_1 [s^{n-1}Y(s) - s^{n-2}y_0 - s^{n-3}y'_0 - \dots - y_0^{(n-2)}] + \dots + a_n Y(s) \\ & + \sum_{m=0}^s \bar{K}_m(s) (s^m Y(s) - s^{m-1}y_0 - s^{m-2}y'_0 - \dots - y_0^{(m-1)}) = F(s) \end{aligned}$$

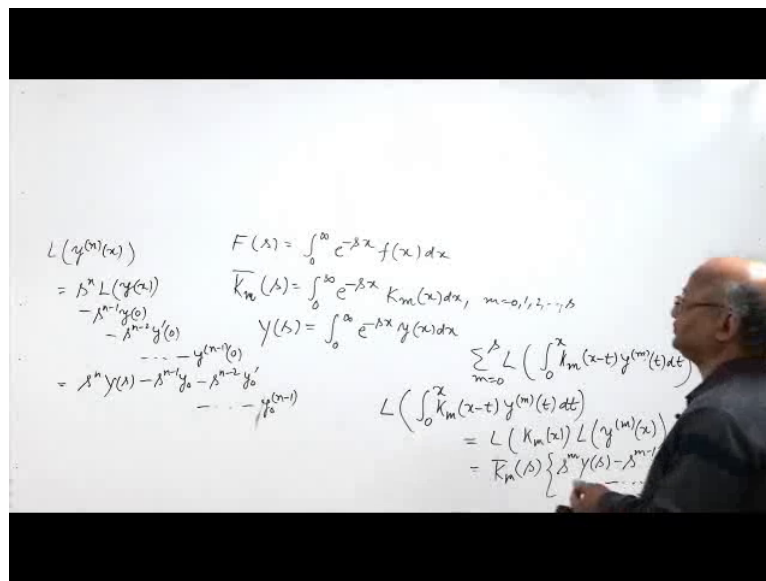

$$\Rightarrow Y(s) \left\{ s^n + a_1 s^{n-1} + a_2 s^{n-2} + \dots + a_n + \sum_{m=0}^s \bar{K}_m(s) s^m \right\} = A(s) \quad \dots(3)$$

NPTEL ONLINE CERTIFICATION COURSE

So let us substitute this value when we take the Laplace transform of $y^{(n)}$ we get s^n to the power n $y(s)$ minus $s^{n-1}y(0)$ minus $s^{n-2}y'(0)$ and so on minus $y^{(n-1)}(0)$ and then a 1 times Laplace transform of $(n-1)$ th derivative of y with respect to x .

So we have s^n to the power $n-1$ $y(s)$, minus $s^{n-2}y(0)$ and so on $y^{(n-2)}(0)$ and so on we have a Laplace transform of $y(x)$ which is $y(s)$ so a n into $y(s)$. And then we have $\sum_{m=0}^{n-1} (-1)^m s^{n-m-1} y^{(m)}(0)$ Laplace transform of this integral.

(Refer Slide Time: 05:18)

So we have $\sum_{m=0}^{n-1} (-1)^m s^{n-m-1} y^{(m)}(0)$ Laplace transform of $\int_0^x k_m(x-t)y^{(m)}(t) dt$.

Now let us write the Laplace transform of $\int_0^x k_m(x-t)y^{(m)}(t) dt$ we applied convolution theorem here Laplace transform of $k_m(x-t)$ into Laplace transform of $y^{(m)}(t)$ dt. So by applying convolution theorem Laplace transform of $\int_0^x k_m(x-t)y^{(m)}(t) dt$ is Laplace transform of $k_m(x)$ into Laplace transform $y^{(m)}(x)$.

Now this is $\bar{k}_m(s)$ and this is again we apply the formula so s^m to the power m $y(s)$ minus $s^{m-1}y(0)$ and then we have $y(0)$ which is $y(0)$ s to the power $m-2$ $y'(0)$ and so on minus s to the power $m-1$.

(Refer Slide Time: 07:00)

Further, let the Laplace transform of $y(x)$ be $Y(s)$.
 Then, taking the Laplace transform of both sides of (2), we get

$$\begin{aligned} & [s^n Y(s) - s^{n-1} y_0 - s^{n-2} y_0' - \dots - y_0^{(n-1)}] \\ & + a_1 [s^{n-1} Y(s) - s^{n-2} y_0 - s^{n-3} y_0' - \dots - y_0^{(n-2)}] + \dots + a_n Y(s) \\ & + \sum_{m=0}^s \bar{K}_m(s) (s^m Y(s) - s^{m-1} y_0 - s^{m-2} y_0' - \dots - y_0^{(m-1)}) = F(s) \end{aligned}$$

$$\Rightarrow Y(s) \left\{ s^n + a_1 s^{n-1} + a_2 s^{n-2} + \dots + a_n + \sum_{m=0}^s \bar{K}_m(s) s^m \right\} = A(s) \quad \dots(3)$$

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE

So we will get sigma m equal to 0 to s k m bar (s) into [s m (bar) y(s) minus s m y(s) y 0 and so on y 0 m minus 1] and Laplace transform of the right side is f x, Laplace transform of f (x) we have assumed as F(s). So we get F(s) here .

Now what we do is we collect the quotient of y(s) so when we collect the quotient of y(s) what we have s to the power n then a 1 times s to the power n minus 1 and then and so on a 0 is and so on a n we have and then sigma m is equal to 0 to s k m bar (s) into s to the power m. The remaining thing is a function of s we can write it as a s.

(Refer Slide Time: 07:50)

where $A(s)$ is some known function of s .
 We determine $Y(s)$ from equation (3) and then take the inverse Laplace transform to obtain the desired function $y(x)$ i.e. the solution of the equation (1).

Example: Consider the integro-differential equation

$$\phi''(x) + \int_0^x e^{2(x-t)} \cdot \phi'(t) dt = e^{2x}, \phi(0) = \phi'(0) = 0 .$$

IT ROOKEE NPTEL ONLINE CERTIFICATION COURSE

So we get the value of $y(s)$ from here $A(s)$ is a known function of s . So we determine $y(s)$ from this equation 3 and then take the inverse Laplace transforms.

Inverse Laplace transform of $y(s)$ when we do we obtain the desired function $y(s)$ which is the solution of the equation 1 for example let us consider the integro differential equation $\phi''(x) + \int_0^x e^{2(x-t)} \phi'(t) dt = e^{2x}$, $\phi(0) = \phi'(0) = 0$. So it is an integro differential equation.

(Refer Slide Time: 08:55)

The image shows a whiteboard with handwritten mathematical work. The equations are as follows:

$$\phi''(x) + \int_0^x e^{2(x-t)} \phi'(t) dt = e^{2x}, \quad \phi(0) = \phi'(0) = 0$$

$$\mathcal{L}(\phi''(x)) + \mathcal{L}\left(\int_0^x e^{2(x-t)} \phi'(t) dt\right) = \mathcal{L}(e^{2x})$$

$$\left\{ s^2 \Phi(s) - s\phi(0) - \phi'(0) \right\} + \mathcal{L}(e^{2x}) \mathcal{L}(\phi'(x)) = \frac{1}{s-2}$$

$$s^2 \Phi(s) + \frac{1}{s-2} (s \Phi(s) - \phi(0)) = \frac{1}{s-2}$$

$$\left(s^2 + \frac{s}{s-2} \right) \Phi(s) = \frac{1}{s-2}$$

$$\Phi(s) = \frac{1}{s^2(s-2) + s}$$

$$= \frac{1}{s(s-1)^2}$$

$$= \frac{A}{s} + \frac{B}{s-1} + \frac{C}{(s-1)^2}$$

We are given the initial conditions $\phi(0)$ is equal to 0 $\phi'(0)$ equal to 0 and ϕ is the unknown function. So let us take the Laplace transform of this equation. So Laplace transform of $\phi''(x)$ plus Laplace transform of $\int_0^x e^{2(x-t)} \phi'(t) dt$ equal to Laplace transform of e^{2x} .

Now Laplace transform of $\phi''(x)$ is $s^2 \phi(s) - s\phi(0) - \phi'(0)$ plus by convolution theorem Laplace transform of $e^{2x} \int_0^x e^{-2(x-t)} \phi'(t) dt$ is Laplace transform of e^{2x} into Laplace transform of $\phi'(x)$ and Laplace transform of e^{2x} is $1/(s-2)$.

So we have $s^2 \phi(s) - s\phi(0) - \phi'(0)$ is 0 $\phi(0)$ is 0 $\phi'(0)$ is 0 and Laplace transform of e^{2x} is $1/(s-2)$, Laplace transform of $\phi'(x)$ is $s\phi(s) - \phi(0)$ equal

to $\frac{1}{s-2}$, $\phi(0)$ is 0 so we get $s^2\phi(s) + \frac{1}{s-2}\{s\phi(s) - \phi(0)\} = \frac{1}{s-2}$, and what we get is we can simplify this.

So s^2 into $(s-2)$ so $\phi(s)$ equal to $\frac{1}{s^2(s-2)}$ plus $\frac{1}{s-2}$ and what we get is $\frac{1}{s(s-1)^2}$, because this is $s^3 - 2s^2 + s$ so we can take as common and this is $\frac{1}{s(s-1)^2}$ we can break it into partial fractions $\frac{a}{s} + \frac{b}{s-1} + \frac{c}{(s-1)^2}$. And we can determine the values of a, b, c very easily from here.

(Refer Slide Time: 11:53)

Solution: Let $L(\phi(x)) = \Phi(s)$,

then taking the Laplace transform of the given equation, we have

$$\{s^2\Phi(s) - s\phi(0) - \phi'(0)\} + L(e^{2x})L(\phi'(x)) = L(e^{2x})$$

$$s^2\phi(s) + \frac{1}{s-2}\{s\phi(s) - \phi(0)\} = \frac{1}{s-2}$$

$$\phi(s) = \frac{1}{s(s-1)^2} = \frac{1}{s} - \frac{1}{s-1} + \frac{1}{(s-1)^2}$$

IT ROOKIEE NPTEL ONLINE CERTIFICATION COURSE 7

When we determine the values of a, b, c we notice that this is $\phi(s)$ $\phi(s)$ is $\frac{1}{s(s-1)^2}$ and this is $\frac{1}{s} - \frac{1}{s-1} + \frac{1}{(s-1)^2}$ whole square.

(Refer Slide Time: 12:07)

So a comes out to be 1 and b is minus 1 c is 1 we can easily find those values. So this 1 over s plus 1 over (s minus 1) and 1 over (s minus 1) whole square. Now let us take the inverse of Laplace transform.

So inverse Laplace transform of phi(s) equal to inverse Laplace transform of 1 over s minus inverse Laplace transform of 1 over (s minus 1) plus inverse Laplace transform of 1 over (s minus 1) whole square. Now inverse Laplace transform of 1 over s is 1 and inverse Laplace transform of 1 over s minus 1 is e to the power x we have to find the inverse Laplace transform of 1 over (s minus 1) whole square.

So for that let us recall the formula if Laplace transform of f(t) is equal to f(s) then Laplace transform of t f(t) is minus d over ds of F(s). So we know that Laplace transform of e to the power t is 1 over (s minus 1). So Laplace transform of t times e to the power t is minus d over ds of 1 over (s minus 1). So this is minus 1 over (s minus 1) whole square so we get 1 over (s minus 1) whole square.

So inverse Laplace transform of 1 over (s minus 1) whole square is e to the power t, here we will have x e to the power x. So now inverse Laplace transform of phi(s) is phi(x) so we get phi(x) as 1 minus e to the power x plus x e to the power x which is the solution of the integro differential equation. We can check that phi(0) is equal to 0 because it is 1 minus 1 plus 0. And we can also see that phi dash(0) is 0.

So it is the solution of the given integro differential equation 1 minus e to the power x plus x e to the power x.

(Refer Slide Time: 14:59)

Another example we can take so y dash(t) equal to sin(x) y dash(t) equal to sin(t) plus integral 0 to t y(t) minus x cos x dx and y(0) is equal to 0. So here again let us assume that Laplace transform y(t) is y(s) and then let us take the Laplace transform of both sides of the given equation.

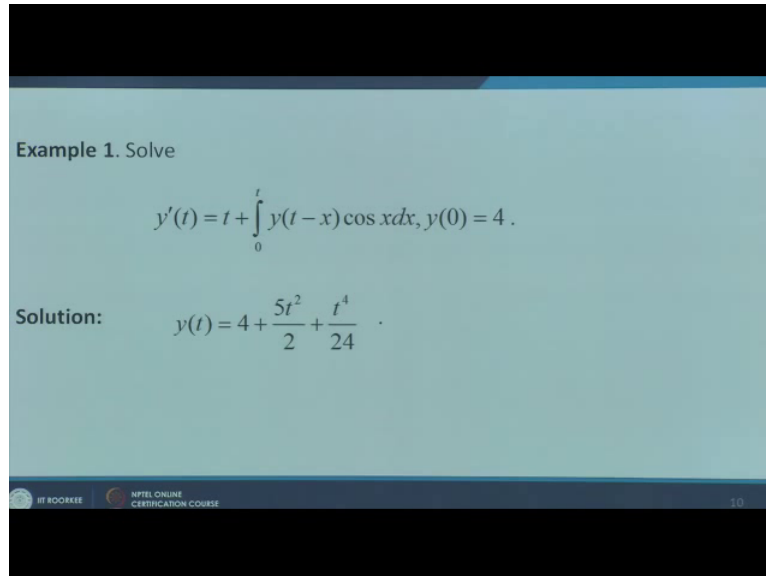

So Laplace transform of y dash(t) will be s y(s) minus y(0) and Laplace transform of sin(t) is 1 over s square plus 1 plus Laplace transform of 0 to t y(t minus x) into cos x dx. Now y(0) is given as 0 so s y(s) 1 over s square plus 1, here we apply the convolution theorem so Laplace transform of y(t) into Laplace transform of cos t. So this is 1 over s square plus 1 plus Laplace transform of y(t) is y(s) into s over s square plus 1.

We then simplify and get the value of y(s) from here so s minus 1 s upon square plus 1 into y(s) is equal to 1 over s square plus 1. So we will get s cube plus s we will get this r y (s) equal to 1 over s cube. Let us take inverse Laplace transform, now recall the formula that Laplace transform of t to the power n, if n is a positive integer it is n factorial divided by s to the power n plus 1.

So here we have a (Laplace transform of) inverse Laplace transform of 1 over s ccube will be t square divided by 2 factorial or t square by 2. So y(t) thus y(t) is equal to t square by 2 and it

is the solution of the given integro differential equation. So this is what we have here $y(t)$ equal to t square by 2, ok.

(Refer Slide Time: 18:14)

Let us take one more example of an integro differential equation $y'(t)$ equal to t plus integral 0 to t $y(t-x) \cos x dx$ where $y(0)$ equal to 4.

(Refer Slide Time: 18:30)

So let us see $y'(t)$ is equal to t plus integral 0 to t $y(t-x) \cos x dx$ and we are give $y(0)$ equal to 4. So let us take Laplace transform of both sides of this equation, so Laplace transform of $y'(t)$ equal to Laplace transform of t plus Laplace transform of integral 0 to t $y(t-x) \cos x dx$.

Let us recall the formula for the Laplace transform of $y'(t)$ so Laplace transform of $y'(t)$ is $s y(s) - y(0)$ $y(s)$ is Laplace transform of $y(t)$ and then Laplace transform of t^{-1} is $\frac{1}{s^2}$ plus by convolution theorem Laplace transform of $\int_0^t y(t-x) \cos x \, dx$ is Laplace transform of $y(x)$ into Laplace transform of or rather I say $y(t)$ and then Laplace transform of $\cos t$.

So this is $s y(s) - 4$ because $y(0) = 4$ 1 by s^2 then we have $y(s)$ then we have s over $s^2 + 1$. So let us collect the quotient of $y(s)$, $y(s)$ times s minus s upon $s^2 + 1$ equal to 1 upon $s^2 + 1$ this is $y(s)$ times $s^3 + s$ minus s , so s^3 upon $s^2 + 1$ equal to $4 s^2 + 1$ divided by s^2 .

And so we have $y(s) = \frac{4 s^2 + 1}{s^2 + 1}$ divided by s to the power ϕ . Let us multiply in the numerator we have $4 s^4 + s^2 + 4 s^2 + 1$ divided by s^5 and which is nothing but 4 by s^5 s^2 by s^5 so 5 by s^3 and then 1 by s^5 . So this is $y(s)$.

(Refer Slide Time: 21:52)

The image shows a whiteboard with handwritten mathematical work. On the left, a list of Laplace transforms for powers of t is given: $L(t^n) = \frac{n!}{s^{n+1}}$, $L(1) = \frac{1}{s}$, $L(t^2) = \frac{2!}{s^3}$, and $L(t^4) = \frac{4!}{s^5}$. In the center, it states "Since $L^{-1}(Y(s)) = y(t)$, we have" followed by the expression $y(t) = 4 + \frac{5}{2}t^2 + \frac{t^4}{24}$. On the right, the partial fraction decomposition of $Y(s) = \frac{(4s^2+1)(s^2+1)}{s^5}$ is shown, leading to $Y(s) = \frac{4s^4 + s^2 + 4s^2 + 1}{s^5} = \frac{4}{s} + \frac{5}{s^3} + \frac{1}{s^5}$. The inverse Laplace transform is then calculated as $L^{-1}(Y(s)) = 4L^{-1}\left(\frac{1}{s}\right) + 5L^{-1}\left(\frac{1}{s^3}\right) + L^{-1}\left(\frac{1}{s^5}\right) = 4 + \frac{5}{2}t^2 + \frac{t^4}{24}$.

Now let us recall again the formula Laplace transform of t to the power n is n factorial divided by s to the power $n + 1$. So by that Laplace transform of 1 is equal to 1 over s Laplace transform of t square is 2 upon 2 factorial upon s^3 Laplace transform of t to the power 4 equal to 4 factorial divided by s to the power 5 . So applying these formulas inverse Laplace transform of $y(s)$ will be 4 times inverse Laplace transform of 1 $y(s)$ plus 5 times inverse Laplace transform of 1 $y(s)$ cube plus inverse Laplace transform of 1 $y(s)$ to the power of 5 .

And this will be equal to $4 + \frac{1}{s^3}$ inverse Laplace transform of $\frac{1}{s^3}$ will be $\frac{t^2}{2}$ by 2. So $\frac{5}{s^2}$ inverse Laplace transform of $\frac{1}{s^2}$ will be $\frac{t^3}{6}$ by 4 factorial so $\frac{t^3}{24}$ by 4. And inverse Laplace transform of $y(s)$ is $y(t)$ so we get the solution as $y(t)$ equal to $4 + \frac{5}{2}t^2 + \frac{t^3}{24}$ which is the required solution of the given integro differential equation

This is what I had to say in this lecture thank you very much for your attention.
