**Lecture – 10**  
**Generating system, linear independence and bases**

Come back to the second half of this lecture.

(Refer Slide Time: 00:26)

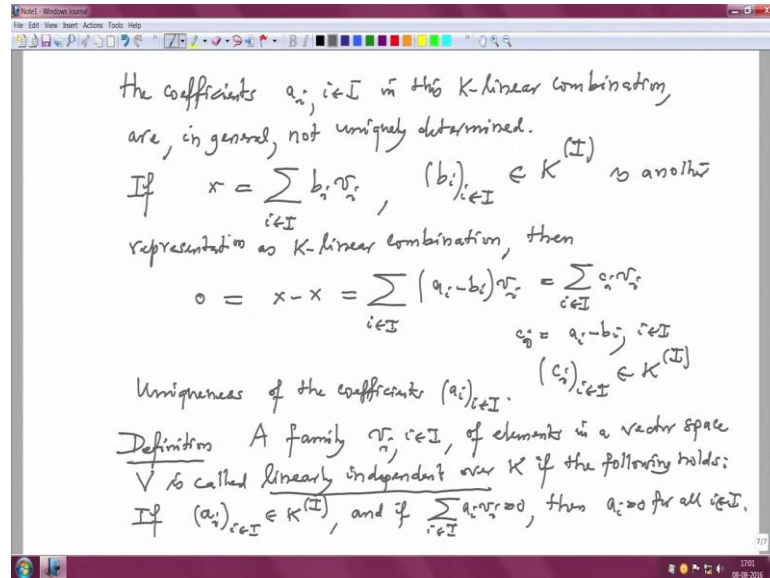

This time I am going to start a new section on generating systems, linear independence and bases. So, as usual let  $V$  be a vector space over an arbitrary field  $K$ . Definition - a family  $v_i, i \in I$  of elements in  $V$  is called a generating system for  $V$  if every element of  $V$  is a  $K$ -linear combination of  $v_i$ 's so that means, every  $x$  in  $V$ , we can write as representation of the form  $x = \sum_{i \in I} a_i v_i$ ,  $i \in I$  and only  $K$ -linear coefficients are nonzero. So, that means, in notation from our clear lectures this is  $(a_i)_{i \in I}$  belongs to  $K^{(I)}$  or which  $a_i$  is equal to 0 for almost all  $i$  so that means, this sum will really finite sum.

Equivalently  $V = \sum_{i \in I} K v_i$ . Remember from one of the earlier lecture this is the notation the right hand side is the notation for the subspace generated by the family  $v_i$ ; and by definition this is or by definition this is the smallest subspace of  $V$  containing all the

elements  $v_i$ . So, if any time, one wants to check that somebody the generating system for  $V$ , we need to check that  $V$  is the only subspace which contain all this guys.

(Refer Slide Time: 05:14)

So, the coefficients in this representation, the coefficients  $a_i$ 's in this linear combination  $K$ -linear combination, are, in general, not uniquely determined. For example, if  $x$  are the another representation submission  $b_i v_i$  where the tuple  $b_i$  is in  $K$  power  $I$  - round bracket  $I$  is another representation as  $K$ -linear combination, then  $0$  will be equal to  $x$  minus  $x$ , and when we collect the coefficients you can rewrite the difference as  $i$  in  $I$ ,  $a_i$  minus  $b_i v_i$ , which will be equal to  $c_i v_i$ . I am just calling  $c_i$  equal to  $a_i$  minus  $b_i$  in  $I$ , and this will also be  $c_i$  will also be in  $K$  power round bracket  $I$ .

If  $c$  has a nonzero then you get a representation of  $0$  as a linear combination of  $v_i$  nontrivial. So, if at all there is a different representation then it leads to the following new definition. So, the uniqueness of the coefficients  $a_i$  demand the following condition on the family  $v_i$ . What condition, so that is let me put it in a definition form. So, definition a family  $v_i, i \in I$  of elements in a vector space  $V$  is called linearly independent over  $K$  if the following holds. If  $a_i$  is an  $i$  tuple which is in  $K$  power round bracket  $I$  that is almost all  $a_i$ 's are  $0$ , and if the linear combination  $a_i v_i$  is  $0$ , then  $a_i$  should be actually  $0$  tuple  $a_i$  equal to  $0$  for all  $i$  in  $I$ . If the family  $v_i$  satisfy this property which we call it linear independence over  $K$ , then the uniqueness will automatically follow.

(Refer Slide Time: 10:24)

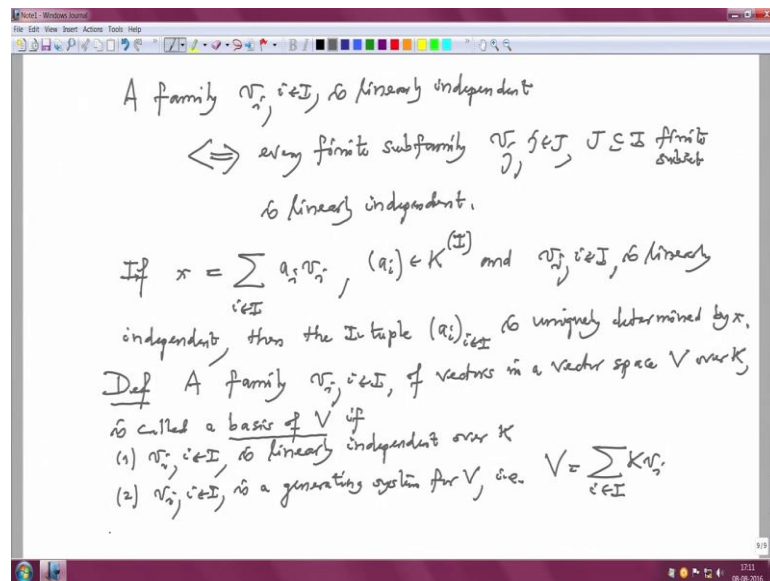

$v_i, i \in I$ , are linearly dependent if they are not linearly independent, i.e.  $\exists (a_i)_{i \in I} \in K^{(I)}$  with  $\sum_{i \in I} a_i v_i = 0$   
 $\neq 0$   
 Let  $i_0 \in I$  be such that  $a_{i_0} \neq 0$   
 $0 = a_{i_0}^{-1} \left( \sum_{i \in I} a_i v_i \right) = v_{i_0} + \sum_{\substack{i \in I \\ i \neq i_0}} a_{i_0}^{-1} a_i v_i$   
 $\Rightarrow v_{i_0} = - \sum_{\substack{i \in I \\ i \neq i_0}} (a_{i_0}^{-1} a_i) v_i$   
 Therefore, a system of vectors is linearly independent if and only if no vector in this family can be expressed as linear combination of the remaining vectors. In particular if  $v_i, i \in I$  is linearly independent then  $v_i \neq v_j$  if  $i \neq j$ .

We will say that family  $v_i, i \in I$  are linearly independent, if they are not linearly dependent. So, linearly dependent means so that is there exist an  $i$  tuple  $a_i$  and  $K$  power round bracket  $I$  with the combination linear combination  $a_i v_i$  with  $0$ , while there exist a nonzero, this is nonzero tuple, tuple is nonzero means at least one of the component is nonzero. So, if such a thing exist then let us take let  $i_0 \in I$  is such that  $a_{i_0}$  is nonzero, then you multiply you solve this equation. So, you keep multiply this by  $a_{i_0}^{-1}$ , this is also  $0$ , because this sum was  $0$  and we have multiplied this sum by  $a_{i_0}^{-1}$   $a_{i_0}^{-1}$  exist because  $a_{i_0} \neq 0$  is nonzero element in the field, and therefore, inverse exist.

And this one is now  $i$  can write it as  $v_{i_0}$  plus the remaining guys,  $a_{i_0}^{-1} a_i v_i$  this is  $i \in I$  and  $i$  different for  $i_0$ . And I will transfer this sum to the other side. So, then so that will imply  $v_{i_0}$  equal to  $\sum_{i \in I, i \neq i_0} a_{i_0}^{-1} a_i v_i$  so that means, the element  $i_0$  element in this family is a linear combination of the remaining ones. So that means, in a generating set we do not need these  $v_i$  in  $I$ . So, this says that. Therefore, I will write a consequence therefore, a system of vectors sometimes I call it vectors; sometime I call it elements in a vector space. System of vectors is linearly independent if and only if no vector in this family can be expressed as linear combination of the remaining family or the remaining vectors. In particular, if  $v_i$  family is linearly independent then  $v_i$  cannot be equal to  $v_j$  if  $i$  is different from  $j$ .

So, in linear this will linearly independent family no vector is repeated.

(Refer Slide Time: 16:05)

Also in the trivial remark a family  $v_i, i \in I$ , is linearly independent if and only if every finite subfamily  $v_j, j \in J, J$  is the finite substitute of it. This finite family is linearly independent. So, now going back to the earlier remark, if  $x$  is a linear combination  $\sum_{i \in I} a_i v_i, i \in I, a_i \in K$  and the family  $v_i$  is linearly independent then the tuple  $a_i$  is uniquely determined by  $x$ . So, this leads to the following definition.

So, definition, a family  $v_i, i \in I$  of vectors in a vector space  $V$  over  $K$  is called a basis of  $V$  if one  $v_i, i \in I$ , is linearly independent over  $K$ . Over  $K$  is sometimes I keep it when  $K$  is a fixed field and there is no way to confuse it, but it is a better habit to write always. And two,  $v_i, i \in I$  is the generating system for  $V$ , that is  $V$  equal to the sum of the subspaces which means every element of  $V$  has a representation of a  $K$ -linear combination among of  $v_i$  is not  $x_i, v_i$ .

(Refer Slide Time: 20:19)

If  $\{v_i, i \in I\}$  is a basis of  $V$ , then every vector  $x \in V$  is a linear combination  $x = \sum_{i \in I} a_i v_i$ ,  $(a_i) \in K^{(I)}$  and the coefficients  $a_i \in K, i \in I$ , are uniquely determined by  $x$ . In this case, for  $i \in I$ ,  $a_i$  is called the  $i$ th coordinate of  $x$  w. r. to the basis  $\{v_i, i \in I\}$ .

For  $i \in I$ ,  $v_i^* : V \rightarrow K, x \mapsto v_i^*(x) := a_i$  is called  $i$ th coordinate function on  $V$  w. r. to the basis  $\{v_i, i \in I\}$ .

$$x = \sum_{i \in I} v_i^*(x) \cdot v_i$$

Only finitely many coordinates of any vector  $x \in V$  can be non-zero.

So, if  $v_i$  is a basis, so I can do it in next page. If  $v_i, i \in I$  is a basis of  $V$ , then every vector  $x$  in  $V$  is a linear combination  $x = \sum_{i \in I} a_i v_i$  where  $(a_i) \in K^{(I)}$  and the coefficients  $a_i$  which are relevant in the field are uniquely determined by  $x$ . They are only finite remember they are only finitely many as could be nonzero. So, in this case, for  $i \in I$ ,  $a_i$  is called the  $i$ th coordinate of  $x$  with respect to the bases  $v_i$ . Sometimes these are also called the  $i$ th components, but I would use  $i$ th coordinate, so that means so to put it in a different way.

So, for each  $i \in I$  you get the functions from  $V$  to  $K$ , these I will denote these functions depend on this given bases. So, I will write it  $v_i^*$ . This function is defined arbitrary vector  $x$  in  $V$  goes to  $v_i^*(x)$  that is by definition it is  $a_i$ ; this makes sense because  $a_i$  is uniquely determined. So, these functions are called coordinate functions on  $V$  with respect to the basis  $v_i$ . Of course, we have noted this so I should clean up a little bit, this is only one for each  $i, v_i$  there this is called  $i$ th coordination function.

So, we have as many coordinate functions as there are basis elements. Of course, I have not did address the question whether a arbitrary vector space has a basis or not. This is under the assumption that if it has a basis then this definition makes sense. So, in the next two lectures, I will also be concerned in general question, if  $V$  has a basis or not and if there are two bases of  $V$  then what is the relation between their cardinalities. And we will prove that any two bases of  $V$  are the same cardinality, and this common cardinality will

be called the debentures, but before I do that I want to get used to this function etcetera so on. So, therefore, in this notation each vector  $x$ , we can write it as linear combination of a  $i$ 's and this  $v_i \star x = v_i$ .

Note that only finitely many coordinate of any vector  $x$  in  $V$  can be nonzero. So, the only difference between these and these, I just showed the value of that these  $a_i x_i$  have replaced by  $v_i x$ . So, the reason being you see the right hand side is also now it involves only a bases and  $x$ . When you look at this sum, you one may wonder what is a  $i$ , how do we calculate a  $i$ , but if you write this expression then it is clear from the way of writing that it is depends on  $x$  and the  $v_i$ .

(Refer Slide Time: 26:10)

Moreover, coordinate functions  $v_i^*: V \rightarrow K, i \in I$ ;

For all  $x, y \in V$ , all  $a \in K$

$$v_i^*(x+y) = v_i^*(x) + v_i^*(y) \quad \text{K-linear maps}$$

$$v_i^*(ax) = a v_i^*(x)$$

Theorem Let  $V$  be a  $K$ -vector space and  $v_i, i \in I$  be a family of vectors in  $V$ . Let

$$f: K^{(I)} \rightarrow V$$

be the map defined by

$$(a_i)_{i \in I} \mapsto \sum_{i \in I} a_i v_i.$$

Then

(1)  $v_i, i \in I$ , is a generating system for  $V \iff f$  is surjective

So, moreover this functions  $v_i$  coordinate functions  $v_i \star$ , these are functions on  $V$  with values in  $K$  and there as many as the number of bases elements, they are numbered by the same set. And they are may respect addition of  $V$  and scalar multiplications, so that is for all  $x$  and  $y$  vectors in  $V$  all scalar  $a$  in  $K$ . These two equations  $v_i \star x$  plus  $y$  equal to  $v_i \star x$  plus  $v_i \star y$ , and  $v_i \star a x$  equal to  $a$  times  $v_i \star x$ .

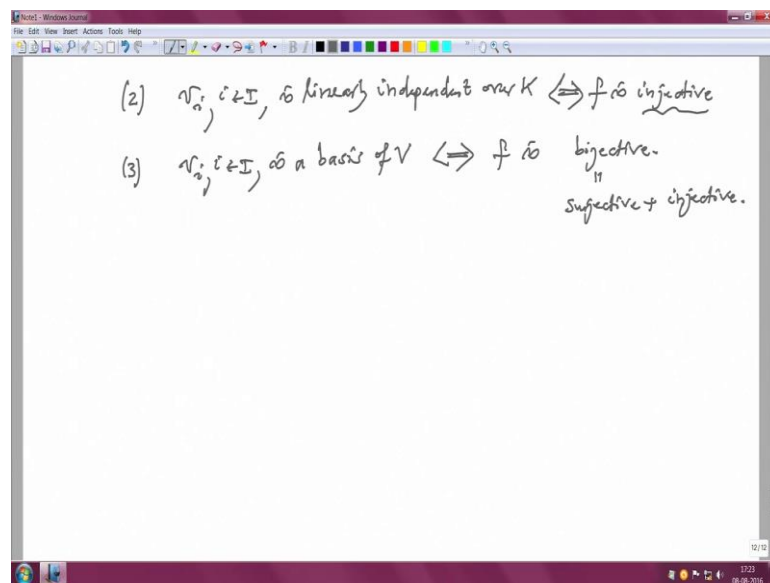

These two equations hold that means, this  $v$  the first means  $v$  is an abelian group homomorphism,  $v$  plus is an abelian group  $K$  plus is also an abelian group and this first equation means its abelian group homomorphism. And second equation means that it respects the scalar multiplication; that means, whether I multiply by a scalar and apply a

coordinate function or I multiply scalar later after applying the coordinate function these two are same.

So, these in general these are called K-linear maps, but overall I just now I do not want to get into this because I still have to deduce some more consequences from the definition of a bases etcetera. So, I will come back to these one of two lectures little late, but right now I want to note what we have observed in the form of theorem. So, theorem, let  $V$  be a vector space,  $V$  be a  $K$  vector space, and let  $v_i$  be a family of vectors in  $V$ . I want to translate all the definitions what we have defined so far generating system linear independence and a bases in terms of the maps.

So, let from  $K$  power  $I$  round bracket  $I$  to  $V$  be the map defined by any  $i$  tuple here, who has only finitely many nonzero entries, map these two to the combination  $\sum a_i v_i$ . This makes sense this is the finite sum because this is an element here, and its each tuple will uniquely determine this combination. Then these are the statements I am writing they are merely the translations of the definitions that we have above; number one  $v_i, i$  in  $I$  is a generating system for  $V$  if and only if the map  $f$  is surjective. So, surjective, let me just recall. So, surjective means every element of  $V$  is in the image of this map I call this map as  $f$  that was indeed the definition of a generating system.

(Refer Slide Time: 30:46)

Second one  $v_i, i$  in  $I$  is linearly independent over  $K$  if and only if  $f$  is injective; injective means two different elements they will have different images. So, this is also clear

because a linearly independent family and vector cannot have two different linear combinations the coefficients are uniquely determined. Third one, combine one and two this side, so  $v_i, i \in I$ , is a bases of  $V$  if and only if  $f$  is a bijective. Bijective means injective and surjective, surjective and injective. So, these are merely the restatements of the definitions. So, from next time, I want to consider many examples which will make this concept more and more clear.

So, thank you till next time.
