Lecture – 54
Determinants (continued)

Now we apply the above determinant theorem and in general the theory of alternating forms to this specific vector space, the standard vector space K^n or also we will write K^I .

(Refer Slide Time: 00:35)

$$K^n = K^I \quad |I|=n, \quad I \subseteq \mathbb{N}_n^*$$

e_1, \dots, e_n standard basis of K^n
 Column-vectors $e_j = (\delta_{ij})_{i \in I}$

$\Delta_e \in \text{Alt}(n, K^n)$ standard determinant function on K^n
 $x_1, \dots, x_n \in K^n$ (column vectors). Then

$A = (a_{ij}) \in M_n(K)$
 $x_j = \sum_{i \in I} a_{ij} e_i$

$$\Delta_e(x_1, \dots, x_n) = \text{Det } A = \sum_{\sigma \in S_n} \text{Sign } \sigma \prod_{j=1}^n a_{\sigma(j)j}$$

Where I has cardinality n or when I is specifically \mathbb{N}_n^* , this is a standard vector space and we have a standard basis e_1 to e_n standard basis of K^n and remember that we are writing these basis elements as a column vectors.

So, e_j is the column δ_{ij} where i is varying in I it is a column; where j th position in that column is one and everywhere else it is 0 and corresponding to these standard basis we will have an alternating form which we have denoted by Δ_e . This is this is an element in $\text{Alt } n, K^n$ this is called a standard determinant function on K^n . Everything is standard because it is with respect to the given coordinate system and what do we have seen in if I take x_1 to x_n columns, column vectors in K^n column vectors arbitrary n column vectors then we have seen Δ_e evaluated on this tuple x_1 to x_n is nothing, but determinant of the coefficient matrix A what is A ? A is the coefficient

matrix a_{ij} this is in $M_n(K)$ and this is a_{ij} s are determined by the equations x_j equal to summation $a_{ij} e_i$ i is from one to n and j is sum 01 to n .

So, these equations define this matrix a and δe evaluated on this column x_1 to x_n tuple is determinant a and also we have seen this is nothing, but this is the definition of the determinant actually. So, this is nothing, but summation, summation in the running over σ permutations of n letters sign of σ , then the product; product is running from j equal to 1 to n $a_{\sigma(j), j}$ this is the determinant.

Ah this is what how we defined the determinant of a matrix square matrix, you take the matrix look at it is columns x_1 to x_n right columns in terms of the standard basis take the coefficient matrix and look at this formula on the right side that is called a determinant and we have also seen that with this definition of determinant of a matrix.

(Refer Slide Time: 04:09)

$$\sum_{\sigma \in S_n} \text{Sign } \sigma \prod_{j=1}^n a_{\sigma(j), j} = \sum_{\sigma \in S_n} \text{Sign } \sigma \prod_{i=1}^n a_{i, \sigma(i)}$$

$$= \sum_{\sigma \in S_n} \text{Sign } \sigma \prod_{i=1}^n a_{i, \sigma(i)}$$

$$= \text{Det } {}^t M$$

$$\begin{array}{ccc} \text{Det} : M_n(K) & \longrightarrow & K \\ M & \longmapsto & \text{Det } M \end{array}$$

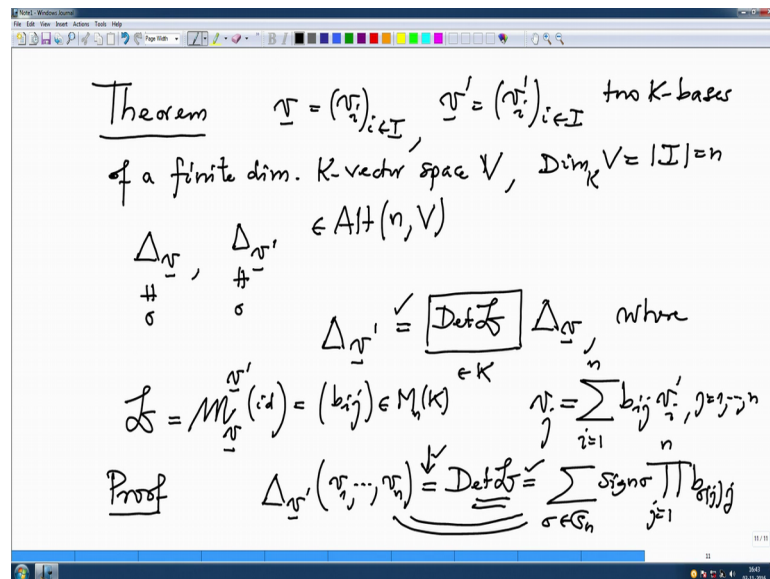

We also know that this formula this sum σ in S_n sign σ product j is from 1 to n , $a_{\sigma(j), j}$ this when I instead of σ I write σ^{-1} in the sum this sum changes to now I will without log I will write the same σ in a later σ in S_n sign of the inverse and sign is original permutation is same. So, this is same as this. So,

If you want write like this σ^{-1} here σ^{-1} here then the product; product is now running from i equal to 1 to n $a_{\sigma^{-1}(i), i}$, but then when I switch to this what will happen is this σ in S_n or this sign is σ in S_n here S_n sign

of sigma product I is from 01 to n a i sigma i. So, this is by definition the determinant of the transpose because the indices of change this is the so, that means, we have define a map det think of det as a map from $M_n(K)$ to K (Refer Time: 05:556) any matrix say map it should determinant and we will study the properties of this map.

So, for example, I want to show that this map preserve the multiplication also these map also characterize the invertible matrices. So, we have some couple of basic things to be proved the following. So, first of all I want to note what happens when you change a basis of the determinant functions.

(Refer Slide Time: 06:27)

So, let us write it is a theorem suppose I have two basis tuples v is one basis tuple v_i , i in I and another is v prime which is numbered by the same indexing said v_i because we know any two basis of a vector space have the same number of elements two K basis of a finite dimensional vector space v K vector space v the dimension of V , is cardinality I which will let us put it n , then we know we have a two determinant functions one corresponding to v delta v and another one corresponding to v prime both are nonzero because this evaluated at v_1 to v_n is one this evaluated at v_1 prime v_2 prime etcetera is. So, the both these are nonzero elements in the vector space $alt\ n\ v$.

So, therefore, one must be a scalar multiple of the other and an I want to find what scalar multiple. So, that scalar multiple I want to find. So, that is I want to write delta v prime

as some scalar multiple, this is some λ in K I will calculate that times Δv prime; that means, this is a scalar multiple of this not v prime v .

I want to find what is that scalar so obviously, how will the scalar will come out from? Scalar will come out from so, called a transition matrix. So, let me write the answer here. So, this answer is determinant of b , where b is the transition matrix from v prime to v of id if you remember this this is nothing, but b_{ij} , and b_{ij} this is a matrix $M_{n \times n}$ in K and this b_{ij} that defined by the equation v_j equals summation $b_{ij} v_i$ prime, i is form 1 to n and j is 1 to n .

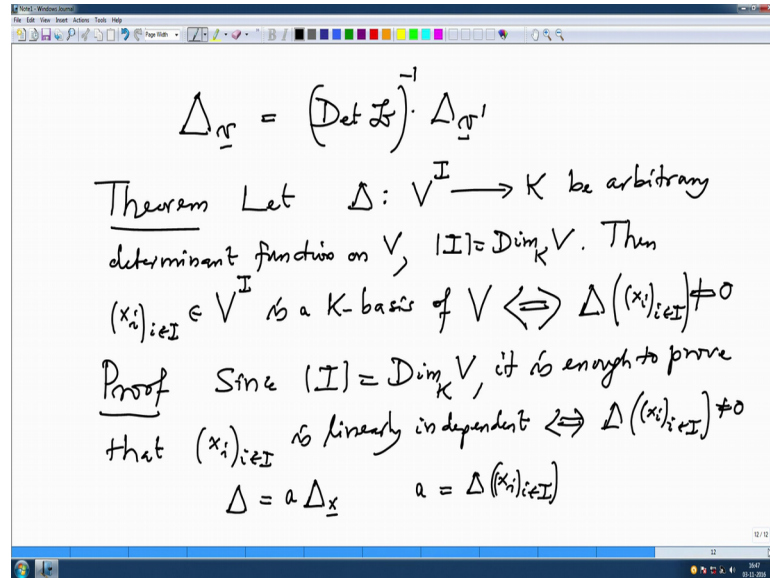

So, when you write a basis vectors in the basis v in terms of the basis vectors in v prime then you get coefficients and that is this coefficient matrix it is called a transition matrix from v prime to v because upper index is always written from where it is, and these are in terms of this you see because of this.

So let us prove this formula this is very easy proof; proof is just only one line. We just every evaluate both sides see these are deter both are alternating maps and they are uniquely determinant by the basis values and we know that Δv prime left hand side Δv prime evaluated at v_i prime i in i is 1 to n this is one that is how this is the determinant function corresponding to this basis, but this is equal to now just plug it no I want to compute sorry I want to compute let us I want to compute left side Δv prime on the basis v_1 to v_n .

This is this side is what if I want to evaluate Δv_1 to v_n this is one and I have to prove that this is. So, enough to note this actually we have to prove this equality once I prove this equality, this equation is clear because you evaluating both sides on v_1 to v_n will give you this and it is uniquely determined by this tuple. So, and this is what this is. So, how do you do this? This is just substitute each v_j here and expand that generalized distributive law and then you will get this value that is summation anymore \sum in σ sign σ product; product is from j equal to 1 to n , $b_{\sigma(j)j}$, but this was precisely the definition of the determinant. So, this is clear and this this equality we know from the general distributive law therefore, this is clear and therefore, this equality is clear everything is very easy.

And now if I want to shift this constant to the other side I know this is b is a transition matrix of the basis from the basis v prime to v , but then it has to be it is invertible matrix because it is a transition matrix.

(Refer Slide Time: 12:43)

We have proved that it is in $\text{gl } \text{gl}_n K$ therefore, also we could write the same equation as same equation we could have written as Δv prime no Δv , Δv equals $\text{det } b$ inverse times Δv prime.

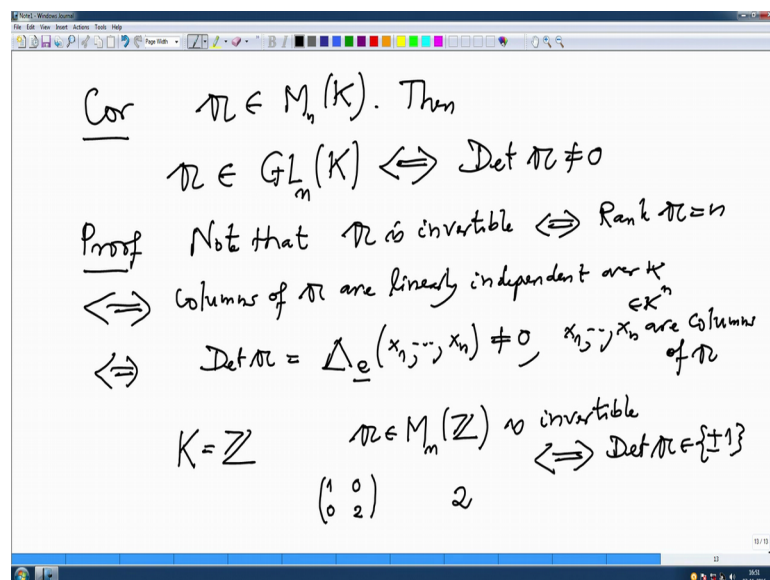

So, I want to specifically note this in a form of theorem. So, let me write this as a theorem, which is very often used. In fact, many people take these has a definition which is not very correct. So, let Δv arbitrary alternating form on v be arbitrary alternating or arbitrary determinant function on v at simply mean this cardinality of I is equal to dimension v and Δ is alternating multi linear and then a tuple x x_i is arbitrary arbitrary tuple in V power I is a K basis of V , if and only if Δ evaluated at the tuple x_i is nonzero.

This is in fact, this is one way to prove that any two basis of a finite dimensional vector space have the same cardinality that is namely the cardinality of you know the smallest cardinality where there is a non zero alternating form already we have. So, proof see there are correct in number. So, I only have to prove either they are linearly independent or a basis or a generating system because the cardinality since cardinality of I equal to

dimension it is enough to prove that the tuple x_i is linearly independent if and only if $\det A \neq 0$. We have already proved that if $\det A \neq 0$, then the tuple x_i is linearly independent. Now we need to prove the converse: if the tuple x_i is linearly independent, then $\det A \neq 0$.

Because of this way or definitely we have proved it, we are proved a contra positive actually we have proved that if the tuple is linearly dependent and the determinant of the tuple is zero and otherwise you see this determinant function if it is a basis this, this if it is a basis then the determinant must be some scalar multiple of the determinant of the tuple, where a is actually the determinant of x_i . So, if a is nonzero that is this is nonzero, then it is a multiple it is a nonzero multiple of this determinant function which is nonzero. So, this is the proof.

(Refer Slide Time: 16:57)

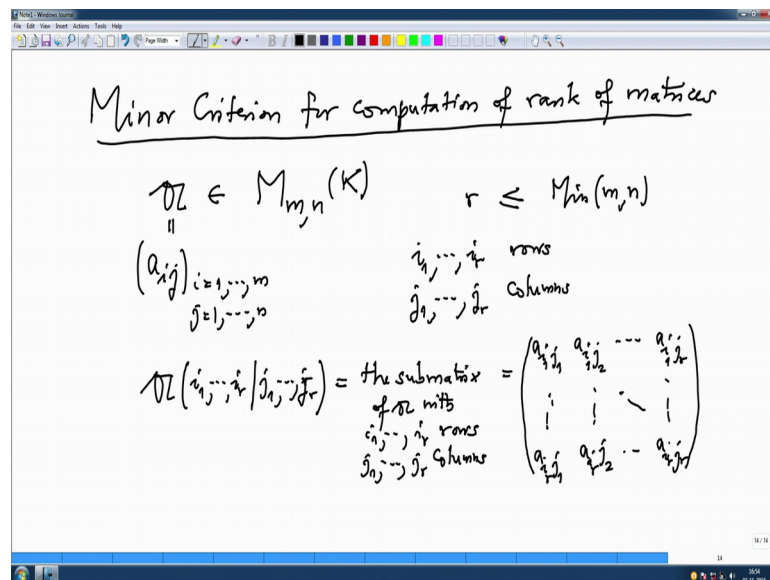

So, when in the corollary in the matrix format suppose you have a matrix A a square matrix then A belongs to $GL_n K$ if and only if determinant of A is nonzero. So, proof note that. So, the definition in $GL_n K$ means A is invertible if and only if rank of A is n that is if and only if columns of A are linearly independent over K , that is if and only if $\det A$ which is by definition the determinant function evaluated at the columns x_1 to x_n is nonzero. So, where x_1 to x_n are columns of A these are in K^n .

So, that I just want to make one very important comment here many people take this as a definition of $GL_n K$ that is should not be; this is a theorem which characterizes invertible matrices by means of this scalar being zero or nonzero. So, this is very important because for example, when you pass on from in general case from a field to arbitrary commutative ring, then it is very important for example, when you take K equal to ring

of integers and you consider a matrices over ring of integers and which matrices are invertible are not the matrices with determinant is a nonzero integer, but matrices with determinant is actually a unit in \mathbb{Z} . So, only possibility is 1 and minus 1. So, matrix A in $M_n(\mathbb{Z})$ is invertible if and only if determinant of A is either plus 1 or minus 1.

So, even for example, if we take two by two matrix say $\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$ here diagonal matrix, the determinant is two and this matrix does not have inversing \mathbb{Z} with integer of entries in \mathbb{Z} , it has one over two will come in the deter in A^{-1} in a denominator of the entries where the matrix does not have integer entries it has only a rational entries. So, in that sense this is very very important to write in this way because for generalization this will come in handy.

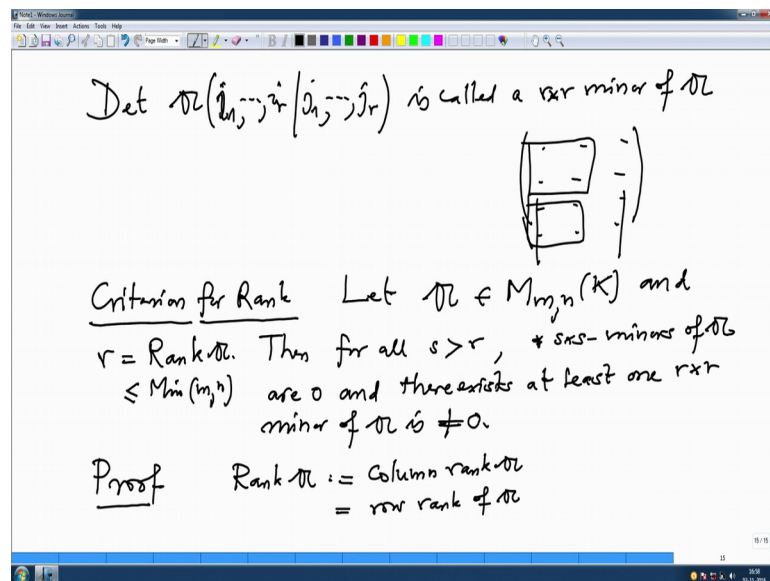

(Refer Slide Time: 20:48)

So, now the last observation here; even the rank we can compute by using determinants. So, that is known as minor criterion for computation of rank of a rank of matrices. So, first let me recall what a minor is. So, when you have a matrix you know this matrix. Now you can take it general matrix A is a matrix with m rows and n columns if let us write this is a_{ij} . So, i is running from 1 to m , and j is running from 1 to n . If I fix any r which is, so rank cannot be more than the minimum and for any r which is less equal to the minimum I want to choose r rows and r columns, and form a sub matrix of the given matrix A so, that I will write it as. So, suppose I choose the rows i_1 to i_r rows and j_1 to j_r columns.

So, I only take those entries from these rows and these columns. So, in that matrix I want to denote by i_1 to i_r j_1 to j_r this is the sub matrix the sub matrix of a , which consists of i_1 to i_r rows and j_1 to j_r columns and j_1 to j_r columns. So, that is also you can write it. So, the first row is i_1 th row. So, $a_{i_1 j_1}$; $a_{i_1 j_2}$; $a_{i_1 j_r}$ and similarly i_2, i_3 i_r ; $i_r j_1, a_{i_r j_2}$ and $a_{i_r j_r}$ actually if you notice lot of energy goes in deciding what is the matrix. So, it is better to deal with the linear maps.

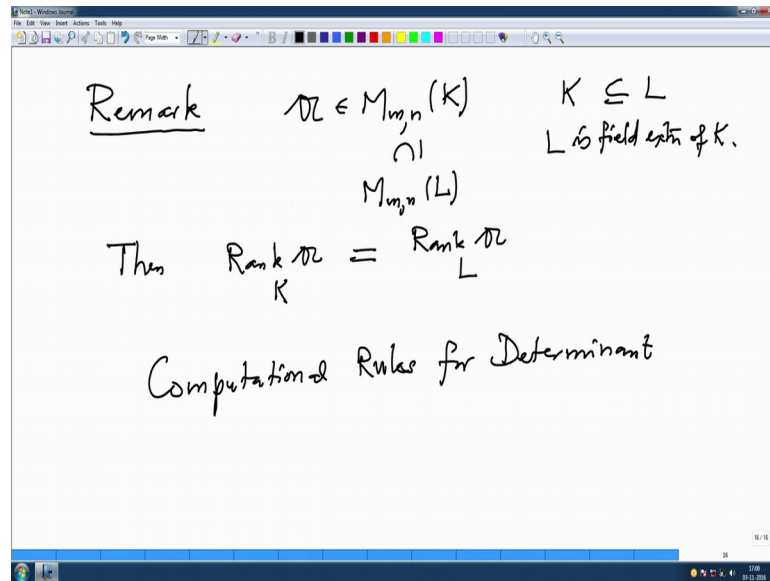

(Refer Slide Time: 24:04)

So this is called r minor of a determinant of this determinant of this square matrix now i_1 to i_r j_1 to j_r this determinant is called a r by r cross r minor of the matrix a . There are many r cross r minors of a see for example, even if you take three by three matrix or four by three matrix this is four rows and three columns. If you want two by two minor it can be this or it can be this or it can be this column with this column and so on there are so many possibilities. So, there are many r cross r minors of the matrix now they are criterion says for rank. So, let a be a matrix with m rows and n columns, and r is a rank of a then of; obviously, we know these r is smaller equal to minimum of m comma n , then for all s bigger than r , s cross s minors of a are 0, all s cross s minor where s is bigger than r they are all zero and there exists at least one r cross r minor of a is nonzero then the rank is r .

So, proof this is I will not give the details, but I will just remind you that remember for doing the rank we have proved that rank of a the definition was the column rank that is the number of maximum number of columns, which are linearly independent and we have proved that by going to the transpose we have proved that this is same as the row rank. So, use this act to check this this is very easy to check.

(Refer Slide Time: 27:38)

Now I will also want to make one remark which I do not remember if I made it earlier, but it is very important. Suppose we have a matrix a m cross n matrix $M \in M_{m,n}(K)$ matrix and K is a field and suppose I enlarge the field L is a. So, L over K L is a field extension of K then; obviously, I can also consider these as a matrix this is contained in $M_{m,n}(L)$ this is a matrix with entries in L also a typically rational matrix you can think as a real matrix or rational matrix you can think as a complex matrix.

Then rank of M as a consider as a K matrix and rank of M in L consider as a matrix in $M_{m,n}(L)$ or L these two ranks are same, this is very very important these are already we have applied these in a Gaussian elimination also when I said that if you have a system of linear equations with rational coefficients if it has a complex solution does it have a rational solution answer is yes it has a rational solution also, so this ok.

So, then next time I will consider how do we make competition with the determinant. So, next time we will do computational rules, rules for determinant; where I will also prove I

will we will also consider adjoint of a matrix and determinant adjoint formula and so on,
so next time.

Thank you.
