Positive Borel measures

We just saw the statement of the Riesz representation theorem, which tells you that positive linear functionals are actually given by integration against positive measures. So along with it we also get a sigma algebra. So this is going to be very similar to the Lebesgue sigma algebra and Lebesgue measure. So you will see regularity properties et cetera, as we have seen in the case of Lebesgue measure. So we will continue with that.

We will look at the space with a bit more structure. So, if we look at statement of the Riesz representation theorem there are two regularity statements. One is the outer regularity which is true for all sets, but the inner regularity is true only for sets with finite measures. This in fact can be improved, if you assume a little bit more on the space X which is what we will do now and the Euclidean spaces and the spaces we are generally familiar with will satisfy these assumptions.

(Refer Slide Time: 1:36)

So, let us start. So this is the Riesz representation theorem we had written down earlier. So the linear functional is given by an integral that is 1, and the comeback sets are finite measures and

these two are the regularity properties, along with completeness so that much we have. So, now we will look at the space with a little bit more structure or properties.

(Refer Slide Time: 2:09)

Defⁿ: 1) Space X is called σ -cpt if X can be written as a countable union of cpt sets (example \mathbb{R}^k)

2) (X, \mathcal{F}, μ) is said to be σ -finite if $X = \bigcup_{i=1}^{\infty} E_i$ where $E_i \in \mathcal{F}$ and $\mu(E_i) < \infty$ (\mathbb{R}^2 with Lebesgue measure)

3) X -Borel σ -T₂ $\mathcal{B}(X)$. A measure μ on $\mathcal{B}(X)$ is called a Borel measure

Push measure same as product

$E_i \in \mathcal{F}$ $\mu(E_i) < \infty$ (\mathbb{R} with \dots)

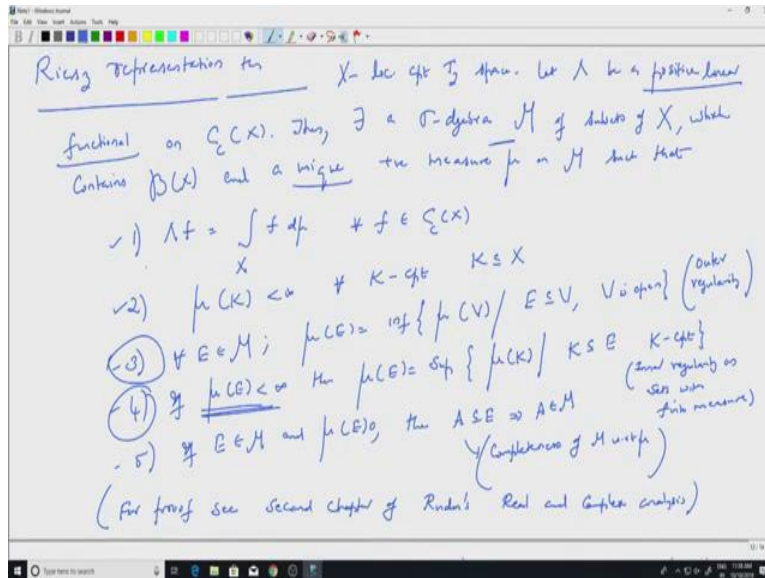

$E \in \mathcal{X}$ E is σ -cpt if $E = \bigcup_{i=1}^{\infty} K_i$ K_i -cpt

$E \in \mathcal{X}$ $E \in \mathcal{F}$ E is σ -finite $E = \bigcup_{i=1}^{\infty} E_i$ $\mu(E_i) < \infty$

4) $E \in \mathcal{M}$ is regular if E is outer regular and inner regular

$\mu(E) = \inf\{\mu(V) \mid E \subseteq V\}$ $\mu(E) = \sup\{\mu(K) \mid K \subseteq E, K \text{-cpt}\}$

5) If all sets in $\mathcal{B}(X)$ are regular then we say μ is regular

So, let me define all the so we will have certain definitions now. The space X is called sigma compact. So, sigma always denotes union countable union. So sigma compact will be that X is, X can be written as a countable, so countable is important, union of compact sets. So you should always check that these assumptions are satisfied for \mathbb{R}^n , so example is \mathbb{R}^k . So that is one definition. Two, a similar definition for measure spaces. So, I have X , f and μ .

Now, I am not asking anything on X , X is simply a space. μ is said to be sigma finite. So you can guess what the definition is going to be. If you can write the whole space to be, union of E_i , i equal to 1 to infinity, where E_i are of course measurable sets and μ of E_i is finite. So there is a way of writing X as a union of sets with finite measures. So, again \mathbb{R}^n with Lebesgue measure will be example, so Lebesgue measure is sigma finite and you can define this for subsets. So both the definitions make sense for both make sense for subsets.

What does it mean? So if I look at E contained in X , E is sigma compact if E is equal to union K_j , j equal to 1 to infinity K_j compact. Similarly, E is contained in X . E is a measurable set, then E is sigma finite. If E is union E_j , j equal to 1 to infinity with μ of E_j finite. So these are natural definitions, extensions to definition to subsets. Now, if X is locally compact $E \subseteq X$ in the whole locally compact $E \subseteq X$ not necessary. We have the Borel sigma algebra of X .

I measure μ on μ of X is called a Borel measure. So that is just to say it is defined on the Borel sigma algebra. It can be defined on a bigger sigma algebra than the Borel set like we have

seen in the statement of Riesz representation theorem. We have the script and which is bigger than the Borel sigma algebra. Now regularity, μ is regular. Well maybe let me start with a set which is regular and then we will go to μ .

So, if I take E in some sigma algebra, let us say μ is regular, so you can compare it with the statement in the Riesz representation theorem. It is regular if E is outer regular, and inner regular. So what is outer regular? $\mu(E) = \inf \{ \mu(V) \mid E \subset V, V \text{ open} \}$. Inner regular, you can approximate from inside by compact sets. So that would be the supremum, $\mu(K)$, K contained in E , K compact.

So this is in the context of Riesz representation theorem and if all sets in \mathcal{M} or in \mathcal{B} of X that is enough, all sets on \mathcal{B} of X , the Borel sigma algebra are regular, then we say μ is regular. So a regular measure is where all sets in \mathcal{B} of X are regular. So, the Riesz representation theorem gives you outer regularity but inner regularity is only for sets with finite measures. But this can be improved with the sigma compactness assumption.

(Refer Slide Time: 7:49)

$\mu(E) = \inf \{ \mu(V) \mid E \subset V, V \text{ open} \}$ $\mu(E) = \sup \{ \mu(K) \mid K \subset E, K \text{ compact} \}$

5) If all sets in $\mathcal{B}(X)$ are regular then we say μ is regular.

Thm: Suppose X is locally compact T_2 , $\mathcal{R} = \mathcal{C}_0(X)$ and μ are given by RRT then

(a) If $E \in \mathcal{M}$, $\epsilon > 0$ \exists a closed F and open set V such that $F \subset E \subset V$ and $\mu(V \setminus F) < \epsilon$. (Compare it with measurability of Lebesgue sets)

(b) μ is a regular Borel measure.

(c) $E \in \mathcal{M}$ $\exists A = F_\sigma$ and $B = G_\delta$ such that $A \subset E \subset B$ and $\mu(B \setminus A) = 0$. E is given by F_σ set and a set of measure zero.

So that is the first result we will do. So, let us state a theorem. Suppose, X is locally compact t_2 and sigma compact. So that is an extra assumption. If μ and ν are given by Riesz representation theorem so RRT, so remember we have five statements there. All of them are true. So that means that we have a locally compact Hausdorff space, that is a linear functional and that is given by μ . So, we have the sigma algebra \mathcal{m} and unique positive measure μ .

So we have these two. Given by Riesz representation theorem then we can say a little bit more. So what are the assertions? One if E is in \mathcal{M} and ϵ positive, then it is a closed set f and open set v such that f is contained in E , contained in V . So you have seen in for the Lebesgue measure and it is exactly the same statement written in one go instead of writing 2-3 statements. $\mu(v) - \mu(f)$ is less than ϵ .

So from the top you can approximate by open sets. From the bottom you can approximate by closed sets. This was the definitions of measurability for, so you can compare it with measurability of Lebesgue measure or Lebesgue sets. That is precisely the statement here. ν is a regular, so now you have both inner and outer regularity because the space is sigma compact. So, μ is a regular Borel measure. C, well from A you know how to deduce this.

This actually implies you have seen in the case of Lebesgue measure. If I take a set in \mathcal{m} and I can approximate it with f sigma and G Delta. So there exist a set A , f sigma and a set B which is G Delta such that A is contained in E , contained in B and of course, the difference between B

and A is 0. So this means that E is given by and f sigma set and a set of measure 0. This is what we did for Lebesgue measure and that is precisely what happens here also. So let us see the proof.

(Refer Slide Time: 11:34)

(b) μ is a regular Borel measure

(c) $E \in \mathcal{M}$ $\exists A = F_\sigma$ and $B = G_\delta$ such that $A \subseteq E \subseteq B$ and $\mu(B \setminus A) = 0$

And that $A \subseteq E$ is given by F_σ set and a set of measure zero

Pf.: X is locally compact $X = \cup K_j$ where K_j are compact

Take $E \in \mathcal{M}$ then $\mu(E \cap K_j) < \infty$ for each j ($\mu(K_j) < \infty$ as K_j is compact)

\exists open set $V_j \supseteq E \cap K_j$ such that $\mu(V_j \setminus (E \cap K_j)) < \frac{\epsilon}{2^j}$

Take $V = \cup V_j$. Then $\mu(V \setminus E) < \sum \frac{\epsilon}{2^j} = \epsilon$

follows from outer regularity. $\mu(A) < \mu(V) + \mu(V \setminus E) < \mu(V) + \epsilon$

5) if all sets in $\mathcal{B}(X)$ are regular then we say μ is regular

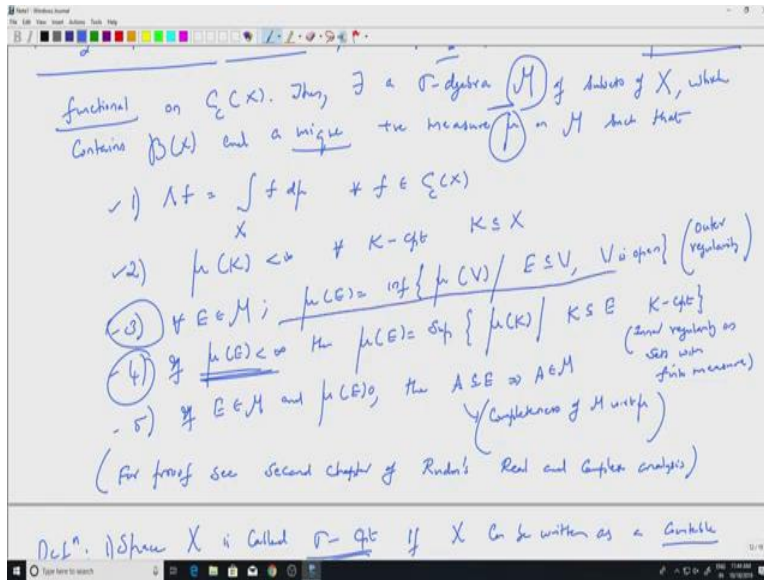

Tho: Suppose X is locally compact T_2 , Γ -compact if \mathcal{M} and μ are given by RRT then

(a) if $E \in \mathcal{M}$, \exists a closed F and open set V such that $F \subseteq E \subseteq V$ and $\mu(V \setminus F) < \epsilon$ (compare it with measurability of Lebesgue sets)

(b) μ is a regular Borel measure

(c) $E \in \mathcal{M}$ $\exists A = F_\sigma$ and $B = G_\delta$ such that $A \subseteq E \subseteq B$ and $\mu(B \setminus A) = 0$

And that $A \subseteq E$ is given by F_σ set and a set of measure zero

So proof follow from whatever properties we know about the measure from the Riesz representation theorem. So, first of all X is sigma compact. So I can write X as $K_1 \cup K_2 \cup K_3 \dots$ where each K_j is compact. That is the sigma compact measure. Now, if I take a set E in M . So let us, let us see what the theorem says. The first assertion if I take a set E , I should be able to find a closed set F and an open set V so that this happens.

So take E in M , then $\mu(E \cap K_j)$ this is finite for every j . Why? Because μ has a property that, $\mu(K)$ is finite for every K which is a compact set. Remember that was part of the Riesz representation theorem. So, if I intersect E with K_j I am going to get something which is contained in K_j and K_j is compact. So that is why. Now because of this there exist, well there exist open set V_j containing $E \cap K_j$, such that $\mu(V_j \setminus (E \cap K_j))$ is less than $\epsilon/2^j$.

So of course you start with fix ϵ positive and all that. You want to say that there are open sets and closed sets which will do something. So well, why is this true? This is simply the definition, the regularity property. So, let us go back to our regularity property. So you can approximate any set from outside. So the third, sorry, let us go back to the Riesz representation theorem.

So this property that infimum of $\mu(V)$, V is open, will give me E . So that is the outer regularity. So this follows from outer regularity. Let us justify this. This follows from outer regularity. Why

is that? So, let us do this for a set which has finite measures. So if I take A such that μ of A is finite, then I know μ of A is, well by outer regularity I know this is a infimum of μ v. A contained in V . V open. But these are finite ones.

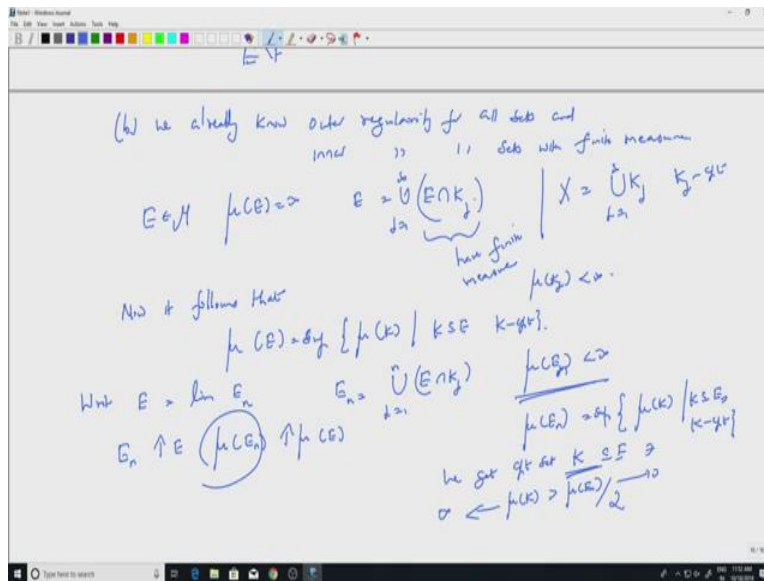

So I have given epsilon there exist to V_j , open, such that μV_j is less than μ of A plus epsilon by 2 the V_j . That is true because of the infimum property. But then this tells me that if we look at μ of V_j to be equal to μ of V_j minus A . Well, A will be contained in V_j plus μ of A because they are disjoint. This tells me that because of μA , μV_j minus μA being less than epsilon 2 j, this implies that μ of V_j minus A is less than epsilon 2 to the V_j .

So, that is why this is true. Alright, so because of this now all that you have to do is take union. So take V to be equal to your union V_j , so this we have done for the Lebesgue measure. Then V minus E , well you can pro that this is contained in, because of the epsilon by 2 to the j et cetera, so I will leave this part to you because we have done this so many times now. So, then μ of V minus E is less than epsilon. Because of epsilon by 2 to the j and you can add them up.

Now how do you get the close set f ? So we have the open set V now. You have to get the closed set, this is exactly the same proof. That is by applying, apply the same thing to E compliment. Apply the same proof to E compliment. So you will get an open set, get W open, E compliment contained in the W and μ of W minus E compliment is less than epsilon by 2. Well, so we have seen this W minus E compliment is equal to w intersection, E compliment, compliment which is W intersection E , equal to E intersection W compliment compliment.

So, take f to be equal to W compliment which is the, which is a closed set. Because W is open and this is simply E minus f so that is all we need. So, this is what we did for Lebesgue measure and that is continues to be true in this abstract setting as well. So what is the next assumption. Let us see. B says it is a regular Borel measure. So that is the next thing we have to prove. So we know that it is outer regular. We know it is inner regular for sets with finite measure. So we what we did was A was proved.

(Refer Slide Time: 18:02)

So let us look at B. We already know regularity for we know outer regularity for all sets and inner regularity for sets with finite measure. So, now if I take some set E in \mathcal{M} , with the property that μ of E is infinity, I can write E as E intersected with K_j union j equal to 1 to infinity. Because remember my space x is sigma compact and X is written as union K_j where K_j compact. But now these are finite measure, finite measure. Well, why is that? Because μ of K_j is finite. So, then it is easy to see that μE is supremum of such things because, so now it follows that μE is the supremum of μ of K where K is contained in E . K is compact. Well, why is that? Let me justify this. So I can write E as so write E as the limit of the increasing union.

So what do I do? So I write E as the limit of let us say E_n . What is E_n ? E_n is j equal to 1 to n E intersection K_j . So, all of this have finite measure. μ of E_n is finite, but E_n increased to E , so μE_n will increase to μE , so I am taking μE to be infinite so μE_n goes to infinite. But E_n have measure finite so μE_n for each E_n is the supremum of μ of K where K is contained in E_n now and K compact by inner regularity because that has finite measure.

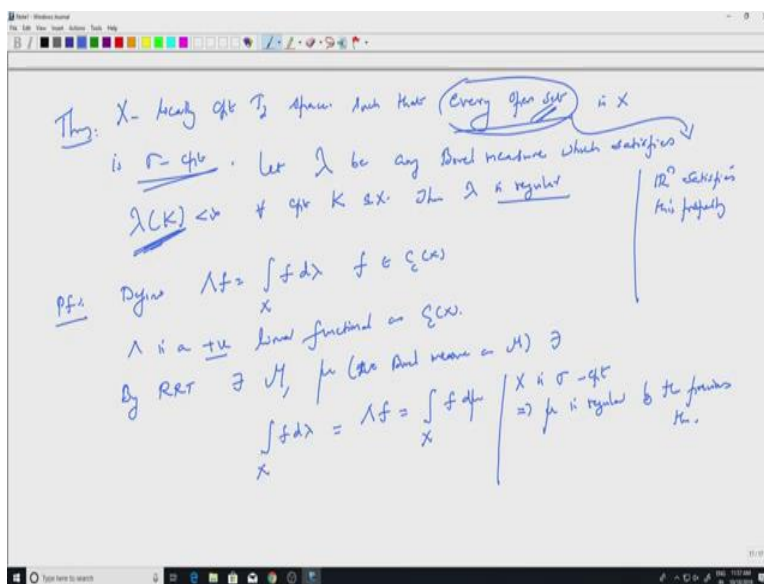

So I can, I have compact sets so we get compact sets K contained in the big set E such that μ of K is greater than μ of E_n by let us say 2 or something like that but this goes to infinity. So the K is compact set contained in E will have μ of K going to infinity which is same as regularity μE is infinity right so the supremum will become infinity. So that is, that is fine. So the c part I

will leave as an exercise because this is what we did for Lebesgue measure once we have the statement a then that implies C by taking appropriate unions and intersection.

You remember, if you recall the proof you will see that you run epsilon over 2 to the power minus K or 1 by j or something like that and you take the union or intersection of those sets that is precisely what will give you this. So a implies b, a implies c. So just assuming that X is sigma compact we are able to conclude that mu is a regular measure, the other two are sort of standard things but regularity of mu is important.

So you see that, it immediate, so we can conclude that the Lebesgue measure is also regular if we know that the Lebesgue measure comes from the Riesz representation theorem in this setting. So we will do that at the so we will construct Lebesgue measure again using Riesz representation theorem and so we will get all these results like regularity and so on.

(Refer Slide Time: 22:47)

So let me state one more theorem which puts an additional condition on the space so X is again locally compact T2 space, such that every open set in X is sigma compact. So any open set is a countable union of compact sets. Let lambda be any Borel measure which satisfies lambda of K to be finite for every compact K, then lambda is regular. So that is a nice thing to have, so the extra property is that if I have an every open set in X sigma compact then any reasonable, so remember this was our reasonable property which we wanted for measures.

Any reasonable measure is a regular measure so in particular Lebesgue measure is a regular measure. If you know that every open set in \mathbb{R}^n is σ -compact but that is a trivial assertion so \mathbb{R}^n satisfies this property. Any open set is the union of close cubes and you can make them compact, so we have seen that. So proof, proof of this usage Riesz representation theorem, so what we do is define so recall this.

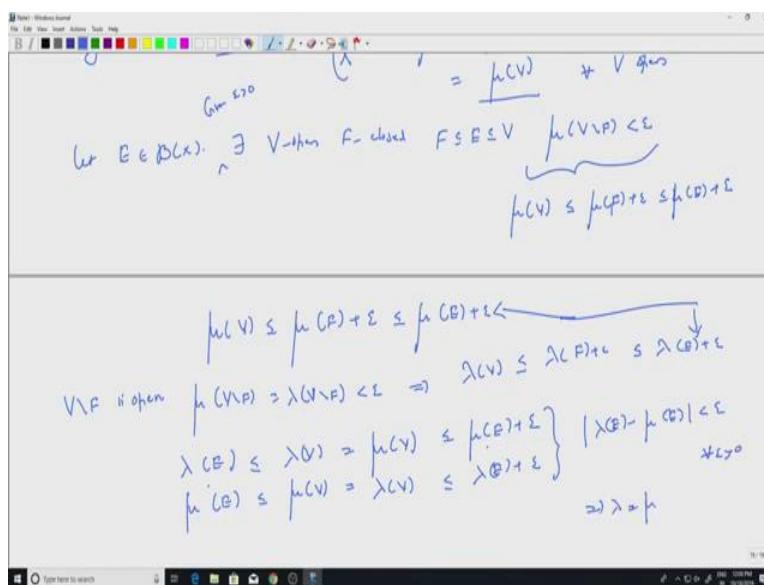

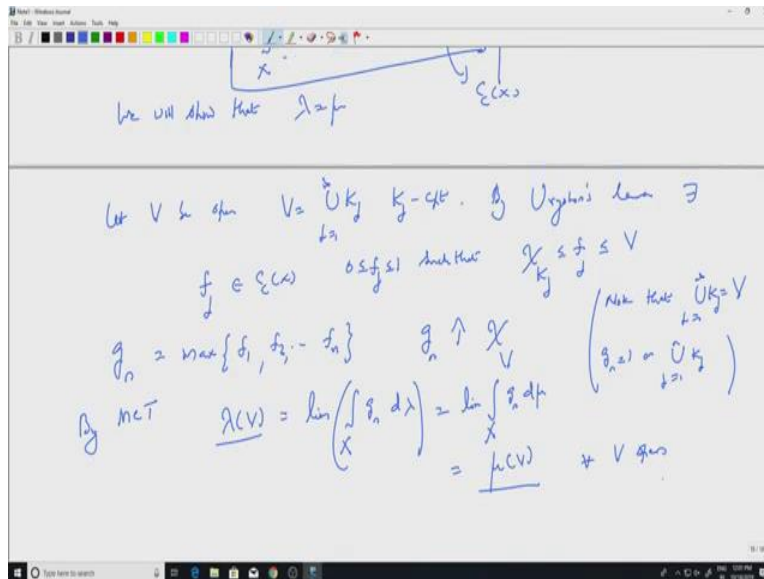

This is a reasonable property and that will define a linear functional. So define $\lambda(f) = \int_X f d\lambda$. So this makes sense, λ is a Borel measure, f is a continuous function, it is in $C_c(X)$. So, it is a linear functional so λ is a linear functional. Well λ is a positive linear functional on $C_c(X)$ because λ is a positive Borel measure.

So by Riesz representation theorem, now this might look a bit confusing but we will, I will explain what this is, by Riesz representation theorem there exist a sigma algebra M and μ , the measure μ positive Borel, positive Borel measure μ on M such that $\lambda(f)$ is given by integration against the measure μ . So measure μ comes from Riesz representation theorem, but we have an additional property here

X is σ -compact, why, because every open set is σ -compact so X in particular is open set so it is σ -compact, implies μ is regular by the previous result, by the previous theorem. So will show that, now look at $\lambda(f)$. $\lambda(f)$ is defined by $\int_X f d\lambda$. So, now we show that these measures are same. So, we know that μ is regular so we will show that λ equal to μ . So we know μ is regular from Riesz representation theorem and the consequences of the Riesz representation theorem just like what we did in the previous theorem.

But the measure λ is given to us and prove that λ is actually equal to μ , then since μ is regular λ is regular. So this is also, so this is something which you should notice. So this tells me that the measure is determined by the class of functions f in $C_c(X)$, if the integrals are same we are saying the measures are same. So, $C_c(X)$ is rich enough to determine the measure. That is what you should understand from this apart from the fact that it is regular. So let us do this quickly.

(Refer Slide Time: 27:50)

Let V be open then I know that V is union K_j , j equal to 1 to infinity K_j compact because any compact set is a sigma compact set. So by Urysohn's Lemma, so recall Urysohn's Lemma there exist, well we have f_j , these are continuous functions and between 0 and 1 such that they are 1 on K_j and they are 0 outside V . Because each K_j contained in V so I have this compact set contained in the open set and I have functions like this by Urysohn's Lemma.

So you take g_n to be maximum of the first n ones f_1, f_2 etcetera, f_n . Then g_n 's are increasing of course, you are taking maximum up to n so g_n plus 1 is maximum up to n plus 1 so it is

increasing. Well it will increase to indicator function of V because K_j is union of K_j is, so this is because note that union of K_j is equal to V . That is one of the things and g_n equal to 1 on union K_j up to n , because you are taking the maximum of 1 over K_j . So you will get 1 there.

So that is the reason. So by Monotone Convergence Theorem $\lambda(V)$, λ is a nice measure, so $\lambda(V)$ is the limit of integral over X g_n $d\lambda$ because g_n converge to χ_V and so by Monotone Convergence Theorem integral over X g_n $d\lambda$ will converge to integral over X χ_V $d\lambda$ which is $\lambda(V)$. But g_n 's are in $C_c(X)$ so this integral, inside integral we know is the integral of g_n with the measure $d\mu$ given by Riesz representation theorem and by this MCT this converges to $\mu(V)$.

So what we have proved is $\lambda(V)$ is equal to $\mu(V)$ for every V open. From this we have to go to Borel sets, so let us do that. So let E be a Borel set, so then there exist V open and F closed such that F is contained in E , contained in V and $\mu(V - F)$ is less than ϵ . So given ϵ of course, given ϵ positive this is true. Well, what does it say? So this tells me that $\mu(V)$ is less than or equal to $\mu(F) + \epsilon$ which is less than or equal to $\mu(E) + \epsilon$.

So, let me write that again. We have $\mu(V)$ less than or equal to $\mu(F) + \epsilon$ less than or equal to $\mu(E) + \epsilon$. Now so that is one such now, $V - F$ is open because F is closed V is open, so $\mu(V - F)$ will be equal to $\lambda(V - F)$ because they agree on open sets. So this will be less than ϵ because $\mu(V - F)$ is less than ϵ and so the above inequality holds. So you will have $\lambda(V)$ less than or equal to $\lambda(F) + \epsilon$ less than or equal to $\lambda(E) + \epsilon$.

So, let us put together these two, this and this put together, you get $\lambda(E)$ less than or equal to $\lambda(V)$ less than or equal to, equal to $\mu(V)$ because V is open and λ is equal to μ on open sets, less than or equal to $\mu(E) + \epsilon$. So we started with $\lambda(E)$ and we are ending with $\mu(E)$. Similarly, $\mu(E)$ I know is less than or equal to $\mu(V)$ but this is equal to $\lambda(V)$ because on open sets they agree which is less than or equal to $\lambda(E) + \epsilon$.

So, now if you put together these two you see the distance between $\lambda(E)$ and $\mu(E)$ is less than ϵ . So this is true for every ϵ positive implies $\lambda = \mu$. So if you have

equality on open sets you can go to other sets using appropriate regularity properties. That is what we have proved. So this is a general proof, you can think of it as a general proof. So we will stop here. What we have done so far is to state down state the Riesz representation theorem, we did not prove it.

It is a long proof, I have referred you to the book by Rudin's Real and Complex Analysis. You can see the proof there. We have looked at consequences of the Riesz representation theorem. So, one of them is that on spaces like \mathbb{R}^n any reasonable measure is going to be a regular measure. So in particular the Lebesgue measure is regular. We already know that it is outer regular on all sets and inner regular on sets with finite measure but with this now we have proved that it is actually regular on all sets. Anyway it will be completed with the construction of the Lebesgue measure in the next few lectures. So, we will start with the construction in the next lecture.
