**Construction of Lebesgue measure**

So, our aim today is to construct the Lebesgue measure using the Riesz representation theory. So, recall that the Riesz representation theorem tells you that a positive linear functional on the space of continuous functions with compact support on a locally compact has of space  $x$ , the place is called  $ccx$ .

If I have a positive linear functional on  $ccx$ , it is given by an integration against the positive measure. Not just that, so the theorem comes with host of other results that you get a sigma algebra which is bigger than the Borel sigma algebra on  $x$ . And there are some regularity properties, which are very similar to what we have seen for Lebesgue measure.

So, what we will do is, we will use continuous functions with compact support on  $\mathbb{R}^k$  to define a linear functional. This is actually the Riemann integral of the function and that will give us a measure which is the Lebesgue measure. And certain regularity properties immediately will follow because  $\mathbb{R}^k$  has a property that every open set in  $\mathbb{R}^k$  is a sigma compact set on such spaces. If you have a measure which is reasonable in the sense that it has finite measure on compact sets, then it is automatically regular we have already done that. So, some of those properties we will follow immediately. So, let us start.

(Refer Slide Time: 1:57)

The image shows handwritten mathematical notes on a whiteboard. The notes are as follows:

- $$\mathcal{P}_n = \{ (x_1, x_2, \dots, x_k) \in \mathbb{R}^k \mid x_i = i \cdot 2^{-n} \text{ for some } i \in \mathbb{Z} \}$$
- $$\mathcal{I}_n = \text{Collection of } 2^{-n}\text{-boxes (cubes with side length } 2^{-n}\text{) with corners in } \mathcal{P}_n$$
- Construct a linear functional on  $\mathcal{C}(\mathbb{R}^k)$

as follows: let  $f \in \mathcal{C}(\mathbb{R}^k)$

$$\Lambda_n f = \sum_{x \in \mathcal{P}_n} f(x) \cdot 2^{-nk}$$
- $f$  - eqly diff'ed  
 $\mathbb{R}^k$  is a finite dim
- $k=1$

$$2^{-n} \sum_{x \in \mathcal{P}_n} f(x)$$

$$= 2^{-n} (f(0) + f(2^{-n}) + \dots + f(1))$$
- length of each interval is  $2^{-n}$
- Diagrams: A number line with points  $0, \frac{1}{2}, 1$  and a function  $f(x)$  graphed above it. A grid diagram showing a unit square divided into smaller squares, with a shaded region representing a set  $A$ .

So, I recall some notation. So, remember the set  $P_n$ ,  $P_n$  was the set of all those points in  $\mathbb{R}^k$ ,  $x_1, x_2, \dots, x_k$  in  $\mathbb{R}^k$  where each coordinate was to the minus  $n$  times in integer. So, each  $x_j$  was  $2^{-n}$  times  $m$  for some  $m$  in integers. And we had  $\omega_n$  to be the collection of, the collection of  $2^{-n}$  boxes, so remember these were cubes with side length  $2^{-n}$ , remember that was a product of intervals of the type  $\alpha\beta$ . It was open on the right hand side remember that,  $2^{-n}$  boxes with corners in  $P_n$ .

So, in the real line case, we have  $1/2$  here,  $1/4$  here and so on, you divide this into half and so on and we are looking at intervals of the type  $[\alpha, \beta)$ . Similarly, for  $\mathbb{R}^2$  and  $\mathbb{R}^3$  and so on, so we had  $0, 1/2, 1/4, 1/8$  and  $1/2, 1/4, 1/8$  and then we divide this into 4 equal parts and this area, which is open on the, this fourth portion is not there. So, such things are called cubes to with corner in coordinates in  $P_n$ .

So, we use this to construct a linear functional, so construct a linear functional on  $C_c$  of  $\mathbb{R}^k$  as follows. Well, how do we do this? This we do this at  $n$ th level and then take limits. So, let  $\lambda_n$  of  $f$ , so  $f$ , I am taking  $f$  in  $C_c$  of  $\mathbb{R}^k$ . So, it is a continuous function with compact support,  $\lambda_n f$  is simply  $2^{-nk}$ .

So,  $2^{-nk}$  is the volume of  $2^{-n}$  box times the sum of  $x$  in  $P_n$ , so we use a different  $P$ , so  $P_n$ , so  $P_n$  is this collection of numbers or coordinates and you sum up  $f$  of  $x$ . This makes sense. So, remember  $f$  is compactly supported, compactly supported, so RHS is a finite sum, RHS is a finite sum. But what exactly is this? Well this is actually a Riemann sum. So, let us look at one particular case in the real line, so that this is much clearer.

So, I take  $[0, 1]$ , so let me write the unit interval to be slightly big and then you go to  $n$ th level, so then I have  $1/2, 1/4, 1/8, \dots$ , et cetera et cetera,  $1/2, 1/4, 1/8, \dots$  something like this. And you are looking at intervals of this form et cetera et cetera. What are we doing? We are, so let us take a take a function which is compactly supported inside  $[0, 1]$ , so I take  $0$  and  $1$  and I have some function here.

So, let us say it is supported inside  $[0, 1]$  and we are forming this sum. So, here the  $k$  is  $1$  because the dimension is  $1$ . So, I am simply looking at  $2^{-n}$  times sum over  $x$  in  $P_n$  of  $f(x)$ . What is this? So, let us  $(6:57)$ , so we are looking at  $k$  equal to  $1$ . And we are looking at  $2^{-n}$  summation  $x$  over  $P_n$  of  $f(x)$ , however we do not have to sum over all the points in  $P_n$  because  $f(x)$  supported in  $[0, 1]$ .

So, we will look at only this area this interval. So what is this, this is equal to 2 to the minus n times, well, I have f 0 that is a point in, 0 is a point in P n, then I have f of 1 by 2 to the n plus et cetera, et cetera, f of 2 to the n minus 1, sorry 2 to the n by n, 2 to the n when f of 1 maybe f of 1 is not included the one before that is included.

So, let us not write this point. I will just put a star to indicate that we are choosing the point here. Alright, so, what exactly is this? So, you look at each interval, each interval has length 2 to the n. So here, length of each interval is 2 to the minus n, so you are multiplying by the length of the interval and the value of f inside that interval. So, that is a Riemann sum.

(Refer Slide Time: 8:34)

The above is a Riemann sum.

$$L(P_n, f) \leq \Lambda_n f \leq U(P_n, f)$$

Change to Riemann integral of f

So define  $\int_a^b f = \lim_{n \rightarrow \infty} \Lambda_n f$  (Riemann integral of f)

It is clear that  $\Lambda$  is linear ( $f, g \in \mathcal{R}(a, b)$ )  $\Lambda_n(f+g) = \Lambda_n f + \Lambda_n g$   
 $\Lambda$  is clearly positive  $f \geq 0 \Rightarrow \Lambda_n f \geq 0$   $\Lambda(f+g) = \int f + \int g$

As follows:

$$\Lambda_n f = \sum_{i=1}^n f(\xi_i) \frac{1}{2^n}$$

different Ritz is a finite sum

$R = 1$

$$\sum_{i=1}^n f(\xi_i) \frac{1}{2^n} = \sum_{i=1}^n (f(\xi_1) + f(\xi_2) + \dots + f(\xi_n)) \frac{1}{2^n}$$

length of each interval is  $\frac{1}{2^n}$

The above is a Riemann sum.

$$L(P_n, f) \leq \Lambda_n f \leq U(P_n, f)$$

Riemann integral of f

So, the above is a Riemann sum. So, in Riemann integral remember, we divide this into intervals. And then we choose, so  $i$ th interval, we choose the supremum and the infimum of the function and then multiply by the length of the interval the value of either the supremum or the infimum.

And this sum we have seen here will be something in between. So, the  $\lambda_n f$  is simply bigger than the lower sum and less than or equal to the upper sum in the case of real line and the similar definitions for  $\mathbb{R}^k$  will make sense, what is  $P$ ?  $P$  is partition of the interval we have here.

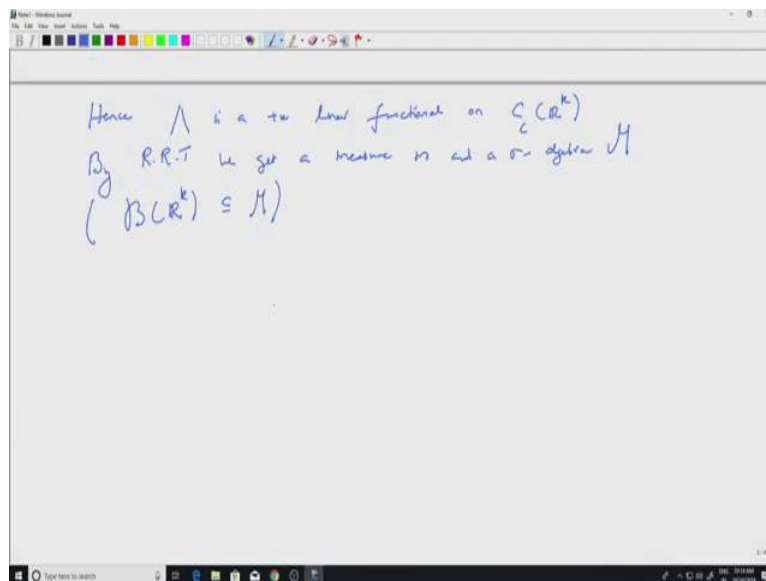

So, and as length of  $P$  goes to 0, we know that this will converge to, so this and this will converge to the Riemann integral of  $f$  because  $f$  is continuous compactly supported. So Riemann integral  $x$  is it will converge. So, similarly the limit of this will exist and that is precise, and that is also the Riemann integral of  $f$ , that is the definition of our linear function.

So, define  $\lambda f$  to be equal to limit  $n$  going to infinity,  $\lambda_n f$ . So, this is precisely the Riemann integral of  $f$ . We are not going to write it that way, but this is what happens. This is true in  $\mathbb{R}^k$  as well in higher dimension as well, if you define the Riemann integral using the boxes instead of intervals.

So, this is now it is clear, it is clear that  $\lambda f$ ,  $\lambda$  is linear. Well, why is that? Because if I take  $f$  and  $g$  in  $cc$  of  $\mathbb{R}^k$  then  $\lambda_n$  of  $f$  plus  $g$ . So, what does  $\lambda_n f$  plus  $g$ ? This is the sum, this is the sum the sum and if it is  $f$  plus  $g$  here, then it becomes some of 2 things and so,  $\lambda_n$  of  $f$  plus  $g$  is  $\lambda_n f$  plus  $\lambda_n g$ .

So, if you take limits, these 2 things will go to  $\lambda$  of  $f$  plus  $g$  that is a definition of  $\lambda$  and  $\lambda f$  here,  $\lambda g$  here and so on, if you to multiply by a constant, the constant will come up. So,  $\lambda$  is linear,  $\lambda$  is clearly positive, clearly positive, why? Because if  $f$  is positive because  $f$  is greater or equal to 0 implies each  $\lambda_n f$  is greater or equal to 0. Because you are adding the values of a positive function here these things are positive so, when you add them, you will get positive numbers and so it is a positive linear function.

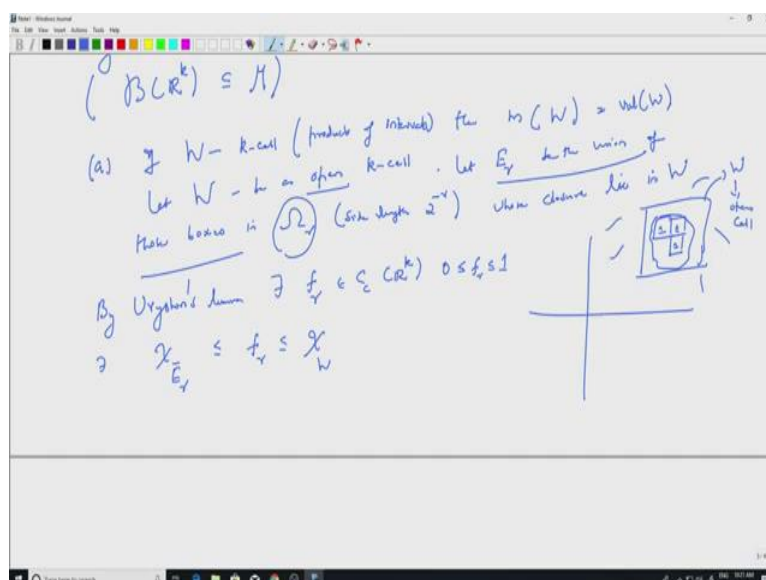

(Refer Slide Time: 12:26)

So hence, so, to conclude what we have done is, lambda is a positive linear functional because it takes values in the real line or in the complex plane depending on where f takes values and as a positive linear functional on the space  $C_c$  of  $R^k$ . So, remember  $R^k$  is locally compact (12:51) et cetera. So, Riesz representation theorem applies.

Hence by Riesz representation theorem. So RRT is representation theorem. We get a measure which we call  $m$  and a sigma algebra  $M$ . So, recall that the Sigma algebra  $M$  is such that the Borel sigma algebra is contained in it that is that comes from the theorem and we have some regularity properties. So, now we prove all the properties which we had stated in the last lectures.

(Refer Slide Time: 13:42)

So, we will start from a. So, the first assertion a, so I will write down what it is and then we will, so a the first assertion was that, if  $W$  is a  $k$  cell, if  $W$  is a  $k$  cell, so  $k$  cell was remember, is the product of intervals rectangle in earlier notation it is productive of interval. Then the measure of the  $W$  is the volume of  $W$ . So, that is the first thing we want the prove. So, let us proof that. So, we start with an open set. Let  $W$  be an open  $k$  cell. So, it is a product of open intervals. Let  $E_r$ , so we have to use the definition of the positive linear functional to conclude this.

So, let  $E_r$  be the union of those boxes in  $\omega_r$ , so remember the side length here was  $2$  to the minus  $r$  whose closure, whose closure lie in  $W$ . So, let  $E_r$  be the union of those boxes in  $\omega_r$ . So, remember that side length is  $2$  to the minus  $r$  whose closure lie in  $W$ . So, we are looking at some  $W$  like this and  $E_r$  is a union of boxes in  $\omega_r$ .

So,  $\omega_r$  gives me a partition of the space with cubes whose corners are in certain prescribed set which we call  $P_r$ . And this will give me some, so we are looking at the union of boxes in  $\omega_r$ . So, we are looking at some boxes like this. Not the ones which go out but whose closure lies inside.

So, remember the  $W$  is an open cell open cell, so the boundary is not included. So, when I take the closure, I do not want to touch the boundary, so things which are strictly inside. So, now by Urysohn's lemma, so by Urysohn's lemma there exist  $f_r$ , which are continuous functions with compact support and they are between  $0$  and  $1$ .

So, these are all part of Urysohn's lemma statement, you already know that such that  $\chi_{\bar{E}}$  closure is less than or equal to  $f_r$  less than or equal to  $\chi_W$  which means that on  $E_r$  it is  $1$ , outside  $W$  it is  $0$ . So, I am looking at something which is  $1$  on these boxes and maybe on a slightly bigger set but it is  $0$  outside  $W$ . So, these are functions given to us by Urysohn's lemma

(Refer Slide Time: 17:27)

Put  $g_r = \max\{f_1, f_2, \dots, f_r\}$ . Then,

$$\text{Vol}(E_r) \leq \lambda_{f_r} \leq \lambda_{g_r} \leq \text{vol}(W)$$

Let  $r \rightarrow \infty$   $\text{Vol}(E_r) \rightarrow \text{vol}(W)$

$\lambda_{f_r} = \int_{\mathbb{R}^k} f_r d\mu$  (RRT)

We get  $\text{vol}(W) \leq m(W) \leq \text{vol}(W) \Rightarrow \text{vol}(W) = m(W)$  + the  $k$ -cell

$B(\mathbb{R}^k) \subseteq M$

(a)  $\exists$   $W$ - $k$ -cell (product of intervals) then  $m(W) = \text{vol}(W)$   
 Let  $W$  be an open  $k$ -cell. Let  $E_r$  be the union of  
 Make boxes in  $\Omega_r$  (side length  $2^{-r}$ ) whose closure lies in  $W$

By Urysohn's lemma  $\exists f_r \in C_c(\mathbb{R}^k)$   $0 \leq f_r \leq 1$   
 $\exists \chi_{E_r} \leq f_r \leq \chi_W$

So, put  $g_r$  is a bar equal to maximum of  $f_1, f_2, \dots, f_r$  for each  $r$ , I have  $f_{sub\ r}$  I am taking the maximum up to  $r$ ,  $f_{sub\ r}$  that I called  $g_r$ . So, then volume of  $E_r$ , is less than or equal to  $\lambda_{f_r}$  less than or equal to  $\lambda_{g_r}$  less than or equal to volume of  $W$ . So, let us try to understand what this is? Volume of  $E_r$  is simply the sum of the volume of the each boxes because they are disjoint. So, you simply add them. Now, so let me draw one more picture to make this clear. So, let us say this is my  $W$ . This is my  $W$ ,  $\mu$  is another color for the boxes inside.

So, I have some boxes here. They are disjoint because you are looking at product of left hand clothes and right hand open sets, so they are disjoint and that this is what forms if I take the

closure, I will get  $E_r$  closure. And well, what is  $f_r$ ?  $f_r$  would be something which is 1 on all this set, so it may be 1 on a slightly bigger set as well.

So,  $f_r$  is something which is 1 here equal to 1 here and  $f_r$  is of course 0 outside  $W$ , it is a compactly supported function. Alright. So, now it is clear that, so what is volume of  $E_r$ ? Well, volume of  $E_r$  will be the sum of those things, some of the boxes. So, you look at these boxes, you add the volume of each of them. That is same as putting 1 here and calculating  $\int f_r$  that is the volume.

But it is 1  $f_r$  is 1 on a slightly bigger set. So, there are more things you are picking up. So, this is obviously bigger than volume of  $E_r$ . And  $g_r$  is of course, greater than or equal to,  $g_r$  is greater than or equal to  $f_r$ . So,  $g_r - f_r$  is positive. So,  $\int (g_r - f_r)$  is also positive and so, we have this inequality and the other one is clear because  $g_r$  is 1 only on the union of sets coming from  $E_1$  to  $E_r$  after that it can be less than 1.

So, volume of  $W$  will be much bigger than  $\int g_r$ . So, this inequality is easy to see, but that is very crucial for us in proving that measure of  $W$  is same as the volume of  $W$ . So, let, now let  $r$  go to infinity. Let  $r$  go to infinity, well what will happen to volume of  $E_r$ ? Well, this will have to go to volume of  $W$ . Well, why is that? So, let us recall what  $E_r$  is.

$E_r$  is the union of all the  $2^{-r}$  boxes inside  $W$ , remember that  $W$  is a disjoint union of boxes from union of  $\omega$ . So, this is because, so because  $W$  is a disjoint because any open set is a disjoint union of sets from union  $\omega$   $r$  or equal to say 1 to infinity, or 0 to infinity.

So,  $E_r$  as  $r$  goes to infinity, so this may be  $E_r$  and when you go to  $E_{r+1}$  you will pick up more smaller ones and so on, so forth. So, I can call this  $E_{r+1}$  and so on and so forth. So, you will fill up other places by taking  $r$ 's bigger and bigger, because the side length becomes smaller and smaller and  $W$  is finally the union of those things.

So, this follows, so on the left hand side, so if you keep this in mind, on the left hand side this  $\int f_r$  converges to volume of  $W$ . And  $\int g_r$ , so what happens to  $\int g_r$ ? Well  $\int g_r$  is  $\int g_r dm$  by this is by the Riesz representation theorem. We have the measure  $m$  and  $g_r$  is a compactly supported continuous function.

So, it is measurable and it, and  $\lambda$  is given by that measure  $m$ . So, this is the representation theorem and this converges to as  $r$  goes to infinity we will go to measure of  $W$

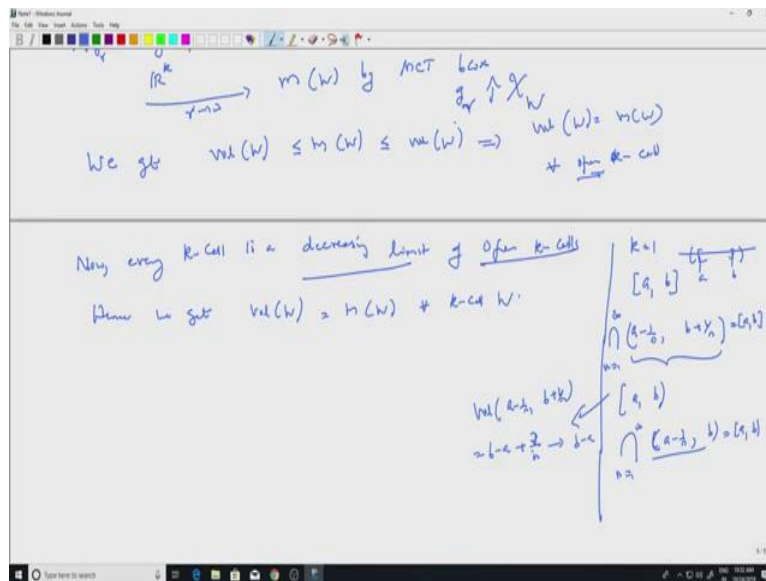

by monotone convergence theorem. Why is that? Because  $g_r$  increases to the indicator function of  $W$ .

Well let us see why, what is  $g_r$ ?  $g_r$  is maximum of  $f_1, f_2, f_3$  and so on. So,  $g_r$ , so remember  $f_1$  would be 1 on 1 boxes,  $f_2$  will be 1 on half boxes and  $f_3$  will be 1 on 2 to the minus 2 boxes and so on and so forth. So, when I take  $g_r$ ,  $g_r$  is the maximum of those things. So, it will be 1 on a large number of boxes completely inside  $W$ . And  $W$  is disjoint union of sets from this, so as  $r$  becomes bigger and bigger,  $g_r$  becomes 1 on a larger and larger set, which finally becomes  $W$  finally converges to  $W$  and so  $g_r$  will converge to the indicator of  $W$ .

So, by monotone convergence theorem,  $\int \lambda g_r$  will converge to  $\int \lambda \chi_W$ . So, from here we get, so, let me write here itself. So, we get volume of  $W$  is less than or equal to measure of  $W$  because the middle term goes to measure of less than equal to volume of  $W$  because the other, this side there is no dependence on  $r$ . So, this implies that volume of  $W$  is same as measure of  $W$ . So, for every open cell, every open  $k$  cell. But this is true for all cells, why?

(Refer Slide Time: 24:47)

Because any now, every  $k$  cell is a decreasing limit of open  $k$  cell, the decreasing limit of open  $k$  cells. So, what does that mean? For example, if I take for  $k$  equal to 1 dimension 1, if I take cell like this, let us say closed interval and this is of course, the intersection of, this is the intersection of, you look at intervals of this form.

So, you can look at  $a - 1/n, b + 1/n$ , you take the open interval and then take the intersection, this is equal to the close interval  $a, b$ . But these are open  $k$  cells they are open

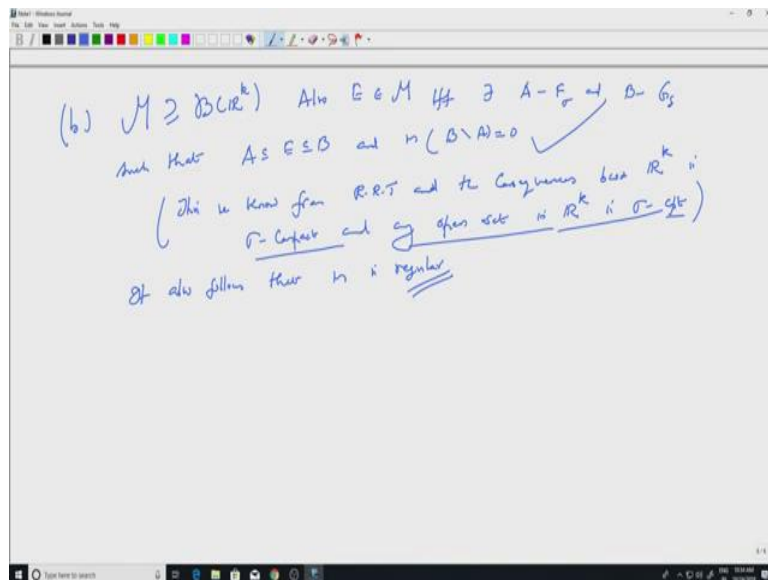

intervals. Similarly, if I have one side open, well then what should I do? I will look at intersection  $n$  equal to 1 to infinity. Open at  $a$  minus 1 by  $n$  and open at  $b$ .

So, these are open cells and intersection would be equal to close at  $a$  open at  $b$ . So, if I know the measure of these things since is a decreasing sequence and the measures are finite, I can apply the theorem we know, if I have an decreasing sequence of sets  $m, E, n$  will converge to  $m E$  if  $E n$  converges to  $E$  or  $E n$  decreases to  $E$  provided one of them has finite measure.

So, that you apply. So, hence we get volume of  $W$ , so that also of course will converge, volume of  $W$  will become, so it is like volume of  $a, n$ , so let us look at this again, volume of  $a$  minus 1 by  $n$  to be plus 1 by  $n$ . This is nothing but  $b$  minus  $a$  plus 2 by  $n$  and of course that converges to  $b$  minus  $a$  whatever the interval is, which is the volume of that interval.

So, we get volume of  $W$  equal to  $m W$ , well  $m W$  because  $m$  is a measure and if you have a decreasing sequence of sets you know it converges, so volume of  $W$  equal to  $m W$  for every cell  $W$ . So, that proves one assertion. So, let me write down the second one, this we already know.

(Refer Slide Time: 27:36)

So, by the assertion b was the Sigma algebra  $M$  we got contains the Borel sigma algebra so this follows from Riesz representation statement of Riesz representation theorem itself. Also, a set belongs to  $M$  if and only if there exist a set  $A$  which is  $F$  sigma and a set  $B$  which is  $G$  delta such that  $A$  is contained in  $E$  contained in  $B$  and  $m$  of  $B$  minus  $A$  is 0. So, this we already know.

So, this follows from this we know from the Riesz representation theorem and the consequences because  $\mathbb{R}^k$  is sigma compact,  $\mathbb{R}^k$  is sigma compact and any open set in  $\mathbb{R}^k$  is also sigma compact in  $\mathbb{R}^k$  is in  $\mathbb{R}^k$  is sigma compact. So, if we have the second assertion that any open set in  $\mathbb{R}^k$  is sigma compact, then the consequences of the Riesz representation theorem, which we looked at the final properties will also be true.

So, this follows immediately from whatever we already know more importantly, it also follows that, it also follows that  $m$  is regular. So, Riesz representation theorem gives you outer regularity and inner regularity for sets with finite measure, but that we have been able to change if the spaces sigma (comp) any open set in  $\mathbb{R}^k$  is sigma compact. So, we can use the second consequence of the Riesz representation theorem to say that any reasonable measure is regular.

So, this directly follows from Riesz representation. So, let us stop here, we have just constructed the Lebesgue measure using the Riesz representation theorem by constructing a positive linear functional on  $C_c$  of  $\mathbb{R}^k$ , what we have just proved tells us that it is actually the Sigma algebra we obtained from Riesz representations theorem is actually the Lebesgue sigma algebra, because it is the sets in the Sigma algebra differ from Borel sets by a set of measure 0. So, it is the completion and it equals the volume of each  $k$  cell. So, we have equality there.

Now, we will look at other properties that it is translation invariant and we know that this is the unique, well we will also prove that this is the unique translation invariant measure on  $\mathbb{R}^k$  which gives finite measures to compact sets. And we will see how it in how the linear transformation affects the measure.

So, remember a constant will come out that constant is actually the determinant which we will prove later on, right now we will prove that if you take a linear transformation Lebesgue set will be mapped into Lebesgue set and its measure is a constant times the measure of the original set.
