**Lecture - 2**  
**Revised Simplex Algorithm**

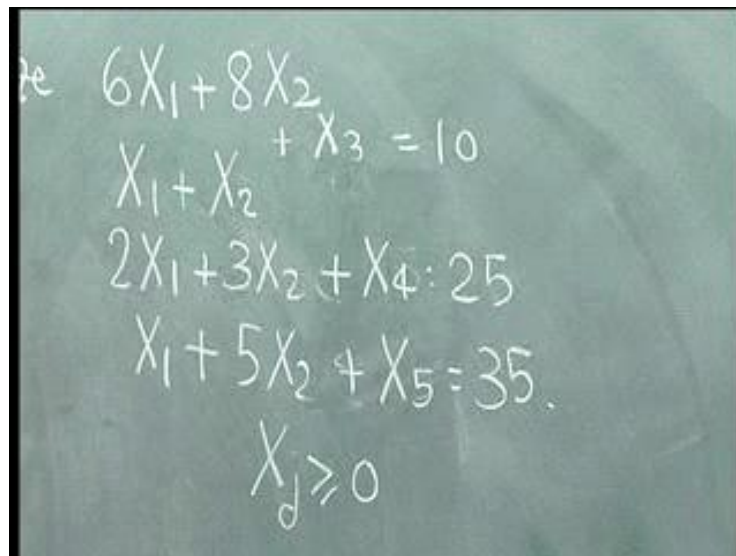

We now explain the details of the revised simplex algorithm using this example.

(Refer Slide Time: 00:24)

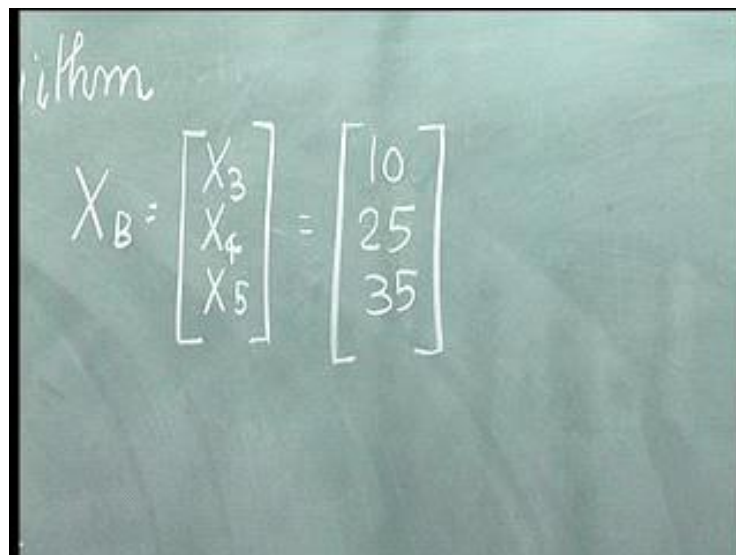

The example problem is to maximize  $6X_1$  plus  $8X_2$  subject to  $X_1$  plus  $X_2$  less than or equal to 10,  $2X_1$  plus  $3X_2$  less than or equal to 25 and  $X_1$  plus  $5X_2$  less than or equal to 35. We have three inequalities and all three are of the less than or equal to type. So, we first convert these inequalities to equations by adding slack variables, plus  $X_3$  equal to 10; instead of this, plus  $X_4$  equal to 25 and we add a third slack variable plus  $X_5$  is equal to 35.

(Refer Slide Time: 00:50)

$$\begin{aligned} & 6X_1 + 8X_2 \\ & X_1 + X_2 + X_3 = 10 \\ & 2X_1 + 3X_2 + X_4 = 25 \\ & X_1 + 5X_2 + X_5 = 35 \\ & X_j \geq 0 \end{aligned}$$

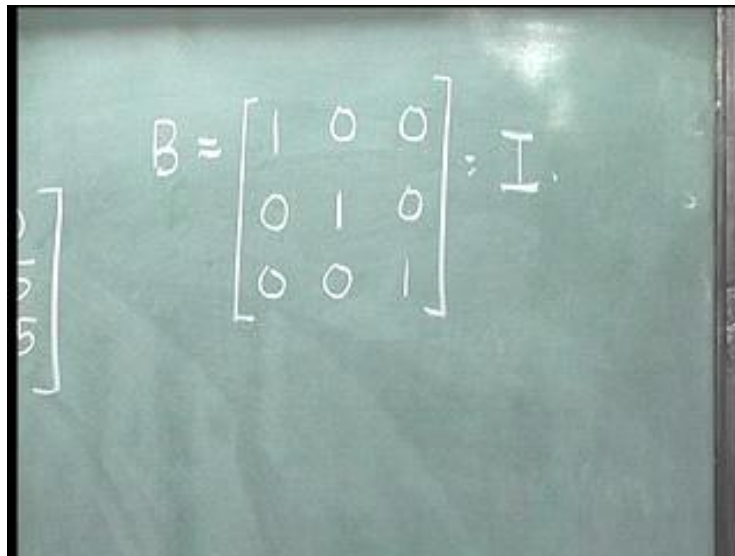

Now,  $X_3$ ,  $X_4$ ,  $X_5$  being slack variables with a plus 1 coefficient and as they appear in only one constraint, so they can qualify to be the basis. We start the simplex algorithm with the  $X_3$ ,  $X_4$ , and  $X_5$  as basic variables.

(Refer Slide Time: 01:38)

$$X_B = \begin{bmatrix} X_3 \\ X_4 \\ X_5 \end{bmatrix} = \begin{bmatrix} 10 \\ 25 \\ 35 \end{bmatrix}$$

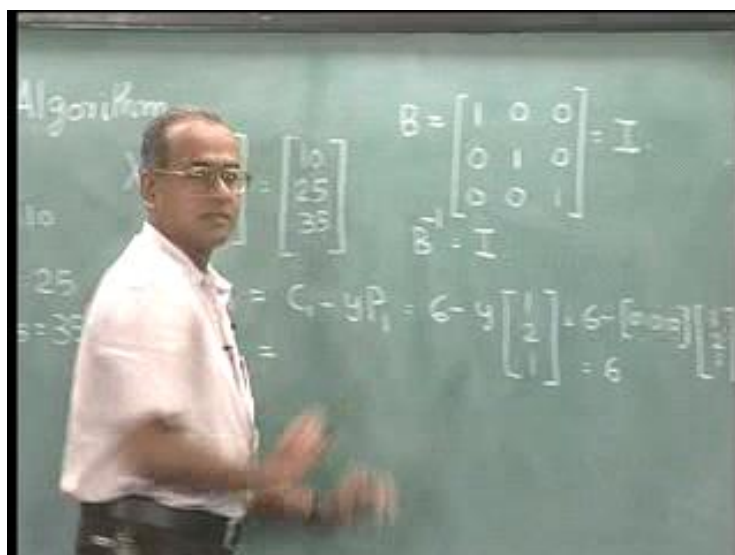

So we say,  $X_B$  set of basic variables is the set  $X_3$ ,  $X_4$ ,  $X_5$  and they will have values 10, 25, and 35. There are two non-basic variables, which are  $X_1$  and  $X_2$ .

(Refer Slide Time: 02:10)

$$B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = I$$

Since  $X_3$ ,  $X_4$ , and  $X_5$  are the basic variables, the basis matrix  $B$  is a 3 by 3 matrix, corresponding to three basic variables and the basis matrix  $B$  will be the matrix 1 0 0, 0 1 0, 0 0 1 which is  $I$ , identity matrix. Since, the basis matrix is an identity matrix,  $B$  inverse is also an identity matrix. Now, in order to check whether this present basis is optimum, we need to look at the two non-basic variables, which are  $X_1$  and  $X_2$  and find out if any one of them can enter the basis.

(Refer Slide Time: 02:51)

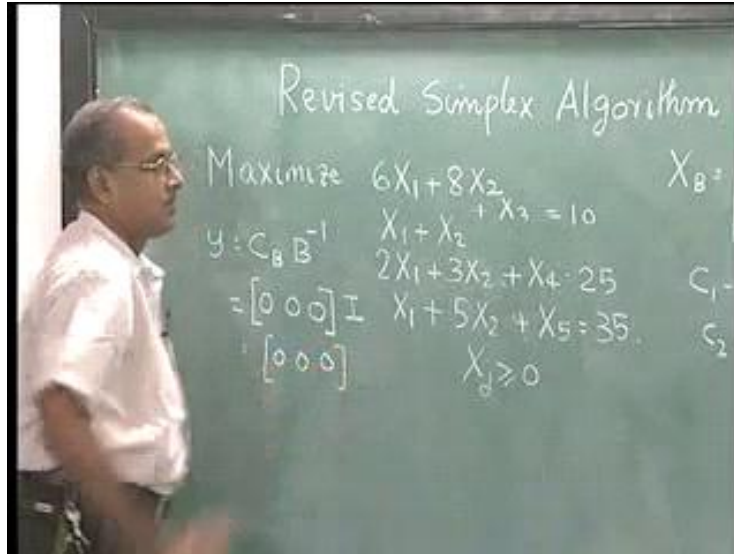

Algorithm

$$B = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} = I$$
$$B^{-1} = I$$
$$C_1 - yP_1 = 6 - y \begin{bmatrix} 2 \\ 1 \end{bmatrix} = 6 - \begin{bmatrix} 2y \\ y \end{bmatrix}$$

To do that, we have to find out  $C_1$  minus  $Z_1$  for variable  $X_1$  and  $C_2$  minus  $Z_2$  for variable  $X_2$ .  $C_j$  minus  $Z_j$  is equal to  $C_j$  minus  $yP_j$ . So,  $C_1$  minus  $Z_1$  is equal to  $C_1$  minus  $yP_1$ .  $Y$  is the value of the dual and  $P_1$  is the vector corresponding to the variable  $X_1$  in the original problem.

Therefore,  $P_1$  will be 1 2,  $P_2$  will be 1 3,  $C_1$  is the objective function coefficient of variable  $X_1$ , which is 6 and  $C_2$  is 8, so this will become 6 minus  $y$  into 1 2 where  $y$  is 1 2.

(Refer Slide Time: 04:06)

$P_1$  is the vector corresponding to variable  $X_1$ . So therefore, that is the vector 1 2 1; so,  $y$  into the vector 1 2 1.  $y$  is the value of the dual variables;  $y$  is given by  $C_B B$  inverse.  $C_B$  is the objective function coefficient of the basic variables. The three basic variables  $X_3$ ,  $X_4$  and  $X_5$ , all of them are slack variables.  $C_B$  is 0. So 0 0 0 into  $B$  inverse is  $I$ , which we have shown here.  $B$  inverse is equal to  $I$ , therefore,  $y$  is equal to 0 0 0. Therefore,  $C_1$  will become 6 minus 0 0 0 into 1 2 1 which is 6.

(Refer Slide Time: 05:11)

In a similar manner,  $C_2$  minus  $Z_2$  will be  $8$  minus  $0\ 0\ 0$ , which comes from the value of  $y$  multiplied by  $P_2$ , which is the vector corresponding to variable  $X_2$ , which is  $1\ 3\ 5$ . So, this will be  $8$  because  $y$  is  $0$ . Now, both  $C_1$  minus  $Z_1$  and  $C_2$  minus  $Z_2$  are positive. Based on the maximum coefficient rule, variable  $X_2$  will enter the basis, because  $C_2$  minus  $X_2$  is  $8$ , which is bigger than  $C_1$  minus  $Z_1$ , so variable  $X_2$  will enter the basis.

(Refer Slide Time: 06:01)

$$C_1 - Z_1 = C_1 - yP_1 = 6 - y$$

$$C_2 - Z_2 = 8 - \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\bar{P}_j = B^{-1} P_j = \begin{bmatrix} 1 \\ 3 \\ 5 \end{bmatrix}$$

Now, in order to find the leaving variable, we need to find the column corresponding to variable  $X_2$  and that is given by  $\bar{P}_j$  is equal to  $B$  inverse  $P_j$  and  $B$  inverse is  $I$ . Therefore  $\bar{P}_j$  will be equal to  $P_j$ , which is  $1, 3$  and  $5$ .  $P_j$  corresponds to  $P_2$ , which is from here  $1\ 3\ 5$ . Now,  $\theta$  is the ratio between right hand side value and the corresponding  $\bar{P}_j$ . So, we should take the minimum of  $10$  divided by  $1$ ,  $25$  divided by  $3$ ,  $35$  divided by  $5$ .

(Refer Slide time: 06:54)

Handwritten mathematical work on a chalkboard. On the left, a column vector is written as  $\begin{bmatrix} 1 \\ 3 \\ 5 \end{bmatrix}$ . To its right, a row vector is written as  $[0 \ 0 \ 0]$ . Below these, three inequality constraints are written:  $10 - \theta \geq 0$ ,  $25 - 3\theta \geq 0$ , and  $35 - 5\theta \geq 0$ . To the right of these constraints, the calculation  $\theta = 7$  is written with an arrow pointing to the right. At the top right, another column vector  $\begin{bmatrix} 1 \\ 3 \\ 5 \end{bmatrix}$  is written, followed by an equals sign and the number 8 with a checkmark:  $= 8 \checkmark$ .

Another way of saying is that, we find out minimum theta, such that 10 minus theta is greater than or equal to 0, 10 minus 1 into theta is greater than or equal to 0, 25 minus 3 theta greater than or equal to 0 and 35 minus 5 theta greater than or equal to 0. This would give us theta equal to 10. This would give us theta equal to 25 by 3. This is 7. 7, is the smallest of the three. Therefore, theta will be equal to 7 and this variable will leave the basis, which means the third variable will leave the basis. So  $X_5$  will leave the basis. At the end of the first iteration, we have understood that we started with  $X_3$ ,  $X_4$ , and  $X_5$  as basic variables and we found out the optimality of this basis and realized that this basis is not optimal, because both of these are positive, which meant that variable  $X_2$  will enter the basis and variable  $X_5$  will leave the basis.

(Refer Slide Time: 08:06)

$$X_B = \begin{bmatrix} X_3 \\ X_4 \\ X_2 \end{bmatrix} = \begin{bmatrix} 3 \\ 4 \\ 7 \end{bmatrix}$$

In the next iteration, the set of basic variables  $X_B$  is now  $X_3$ ,  $X_4$  and  $X_2$ , because variable  $X_2$  has now replaced variable  $X_5$ . Now, the corresponding right hand side value can straight away be given. We have found out from here that theta equal to 7 and the third variable is the one that leaves. So in the next iteration, the variable  $X_2$  will take a value of theta, which is 7, while the rest of the variables will take the corresponding value, when we substitute theta into these two expressions. 10 minus theta is 3, 25 minus 3 theta is 4, so we will have  $X_3$  equal to 3,  $X_4$  equal to 4 and  $X_2$  equal to 7. We can even verify this;  $X_2$  equal to 7,  $X_1$  plus  $X_2$  plus  $X_3$  is equal to 10. So, 7 plus 3 is 10, 3  $X_2$  plus  $X_4$  is 7 into 3 is 21 plus 4 is 25, 5 $X_2$  plus  $X_5$ , 5 $X_2$  is 35 plus 0 is 35.

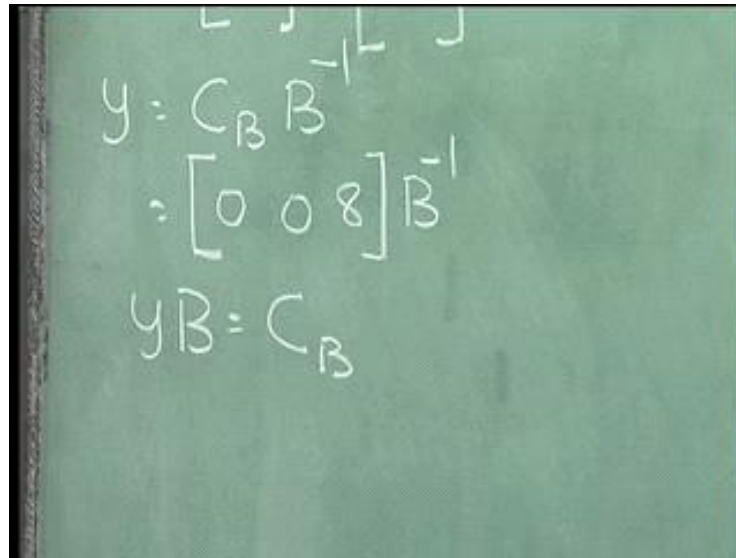

(Refer Slide Time: 09:09)

$$\begin{bmatrix} 1 \\ 3 \\ 5 \end{bmatrix}$$
$$\begin{aligned} 10 - \theta &\geq 0 \\ 25 - 3\theta &\geq 0 \\ 35 - 5\theta &\geq 0 \end{aligned}$$
$$\begin{bmatrix} 1 \\ 3 \\ 5 \end{bmatrix} = 8 \checkmark$$

$\theta = 7 \rightarrow$

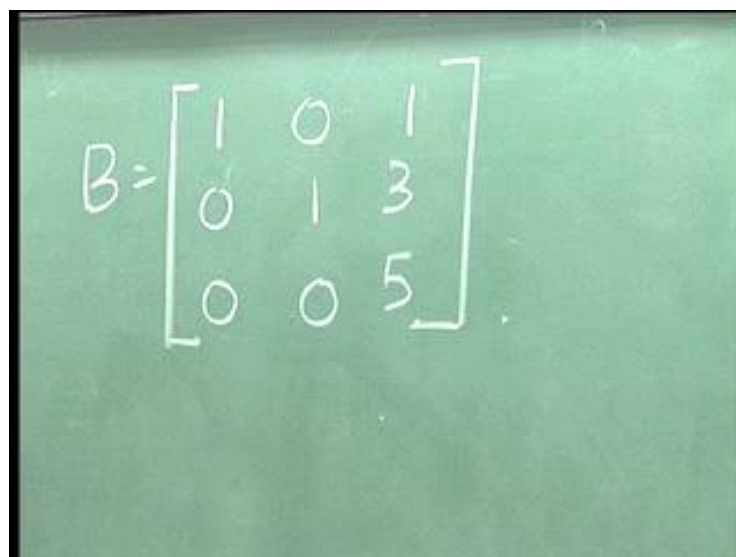

We now have this as the basis and we now have to find out whether this basis is optimal. In order to do that, we need to look at the two non-basic variables, which are  $X_1$  and  $X_5$  and find out their  $C_j$  minus  $Z_j$  values. Before we find the  $C_j$  minus  $Z_j$  values, we first have to find out the value of the dual, which is  $y$ .

(Refer Slide Time: 09:47)

$$y = C_B B^{-1}$$
$$= [0 \ 0 \ 8] B^{-1}$$
$$yB = C_B$$

$y$  is given by  $C_B B$  inverse.  $C_B$  is the objective function coefficient corresponding to the basic variables. This has 0 0 and variable  $X_2$  has 8. So  $Y$  will be 0 0 8 into  $B$  inverse. Another way of looking at it is instead of saying  $y$  is equal to  $C_B B$  inverse, you can always say  $yB$  equal to  $C_B$ . We now know that this basis matrix is a 3 by 3 matrix, corresponding to  $X_3$ ,  $X_4$ , and  $X_2$ .

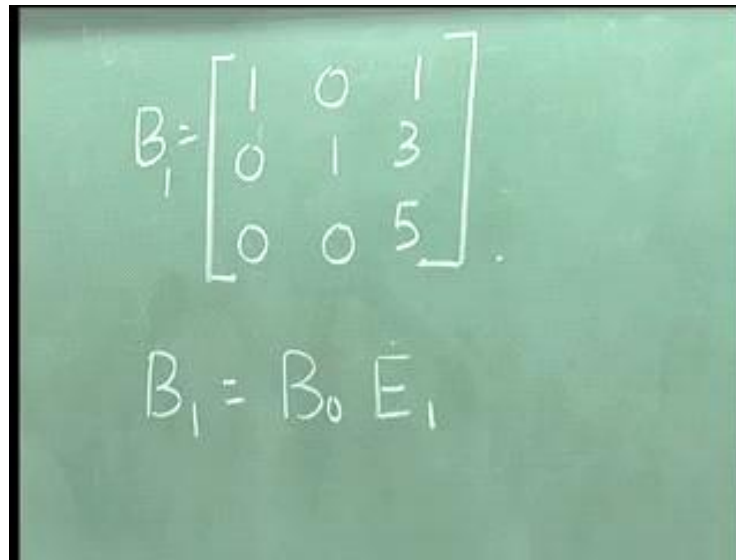

(Refer Slide Time: 10:43)

$$B = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix}$$

The basis matrix  $B$  will be corresponding to  $X_3$ ,  $X_4$ , and  $X_2$ ; so  $1\ 0\ 0$ ,  $0\ 1\ 0$  and corresponding to  $X_2$ , would be  $1\ 3\ 5$ . One way of finding out this  $y$ , is by taking this basis matrix  $B$ , inverting it in the usual way, either by finding out first the determinant and the cofactor and the adjoint and then getting  $B$  inverse or by inverting  $B$  in other ways such as Gauss Jordan method or Gaussian elimination or any of these methods.

(Refer Slide Time: 11:26)

$$B_1 = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix}$$
$$B_1 = B_0 E_1$$

But what we are going to do now is something different. We are not going to directly and explicitly invert  $B$ , but we are going to indirectly invert the basis matrix  $B$ . What we will do now, is we simply call this  $B$  as  $B_1$ , which is the basis matrix corresponding to iteration number one. The earlier  $B$ , which was the starting iteration, is now called  $B_0$ . Now what we are going to do is to say that  $B_1$  is equal to  $B_0$  into  $E_1$  where  $E_1$  is called an Eta matrix. An Eta matrix is also a 3 by 3 matrix. The difference is that, one column of the 3 by 3 matrix is a non-identity column and that non-identity column is exactly the column corresponding to  $P_{bar_j}$ .

(Refer Slide Time: 12:27)

$$B_1 = B_0 E_1$$

$$E_1 = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix}$$

In our case,  $E_1$  is a 3 by 3 matrix. Since, the third variable left the basis, the third column of the Eta matrix  $E$  is a non-identity column. The other two columns are 1 0 0, 0 1 0 and the third column is  $\bar{P}_3$ , which is 1 3 and 5. It happens that  $B_1$  is equal to  $E_1$  and in fact, in all the first iteration  $B_1$  will always be equal to  $E_1$ . Later we will see that, it changes. Now  $B_1$  is equal to  $B_0$  into  $E_1$ . In order to find out  $y$ , we should find out  $yB_1$  is equal to  $C_B$ .

(Refer Slide Time: 13:23)

$$X_B = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} 3 \\ 4 \\ 7 \end{bmatrix}$$

$$B_1 = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix}$$

$$y = C_B B_1^{-1} = [0 \ 0 \ 8] B_1^{-1}$$

$$y B_1 = C_B$$

$$y B_1 E_1 = C_B$$

$$y E_1 = C_B$$

$$[y_1 \ y_2 \ y_3] \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix} = [0 \ 0 \ 8]$$

$$y = [0 \ 0 \ 8/5]$$

$yB_0E_1$  is equal to  $C_B$ .  $B_0$  is  $I$ ; so,  $yE_1$  is equal to  $C_B$ . Now,  $y$  is a vector. So  $y$  is now written as  $y_1 \ y_2 \ y_3$ . Because there are three constraints, there are three basic variables on the primal, there will be three dual variables for  $y$ ; so  $y_1, y_2, y_3$  into  $E_1$ , which is given here 1 0 0, 0 1 0, 1 3 5 is equal to  $C_B$ , which is 0 0 8. The nice thing about writing this way is that the

computations are much simpler, because the first equation will be 1 into  $y_1$  plus 0 into  $y_2$  plus 0 into  $y_3$  is equal to 0.

This is 1 into 3 this is 3 into 3, so the resultant is 1 into 3. So  $y_1$  plus  $0y_2$  plus  $0y_3$  is 0, which would give  $y_1$  as 0. Now the second one,  $0y_1$  plus  $1y_2$  plus  $0y_3$  is equal to 0, would give us  $y_2$  equal to 0.  $y_1$  plus  $3y_2$  plus  $5y_3$  is equal to 8, would give us  $y_3$  is equal to 8 by 5. So  $y$  value is 0 0 and 8 by 5. With the value of  $y$  that we have obtained, we will now go back and find out the  $C_j$  minus  $Z_j$  corresponding to the two non-basic variables, which are  $X_1$  and  $X_5$ .

(Refer Slide Time: 15:23)

$$\begin{aligned}
 C_1 - Z_1 &= 6 - [0 \ 0 \ 8/5] \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix} \\
 &= 6 - 8/5 = 22/5. \\
 C_5 - Z_5 &= 0 - [0 \ 0 \ 8/5] \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} = -8/5.
 \end{aligned}$$

We have to find out  $C_1$  minus  $Z_1$  which is,  $C_1$  is 6 minus  $yP_1$ ;  $y$  is 0 0 8 by 5 into  $P_1$ .  $P_1$  comes from the original matrix, which is the column corresponding to variable  $X_1$  in the original matrix which is 1 2 1. So  $C_1$  minus  $Z_1$  is 6 minus this, into 1 2 1, which is 6 minus 0 into 1 plus 0 into 2 plus 8 by 5, 6 minus 8 by 5 which is 22 by 5. Now  $C_5$  minus  $Z_5$ ; variable  $X_5$  is the slack variable, therefore  $C_5$  is 0 minus  $y$  is 0 0 8 by 5 into  $P_5$ .  $P_5$  comes from here.  $P_5$  is 0 0 and 1, because variable  $X_5$  appears only in this constraint, with the coefficient of 1. It does not appear in these two constraints. So we have 0 0 8 by 5 into 0 0 1, which is minus 8 by 5. So,  $C_j$  minus  $Z_j$  are the two non-basic variables. Non-basic variable  $X_1$  gives us the  $C_j$  minus  $Z_j$  positive value. For variable  $X_5$ , it is a negative value. There is only one positive  $C_j$  minus  $Z_j$  therefore, variable  $X_1$  will enter. Now, once variable  $X_1$  will enter, we now have to find out the leaving variable.

(Refer Slide Time: 17:15)

Handwritten equations on a chalkboard:

$$\bar{P}_1 = B^{-1} P_1$$

$$B \bar{P}_1 = P_1$$

$$E_1 \bar{P}_1 = P_1$$

$$\begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

In order to find out the leaving variable, we need to find out  $\bar{P}_1$  which is equal to  $B^{-1} P_1$ . Once again, we do not have  $B^{-1}$  explicitly computed, so we pre-multiply by  $B$  to get  $B \bar{P}_1 = P_1$ , because  $B B^{-1}$  will give  $I$ , so  $I P_1 = P_1$ . Now this  $B$  is nothing but  $B_0$  into  $E_1$ . We will have  $E_1 \bar{P}_1 = P_1$ .  $B_0$  is also an identity matrix, so this will reduce to  $E_1 \bar{P}_1 = P_1$ . Now  $E_1$  is known,  $E_1$  is here.  $E_1$  is  $1 \ 0 \ 0, 0 \ 1 \ 0, 1 \ 3 \ 5$  into  $\bar{P}_1$  is what we want to find out. We simply call it as some  $a \ b \ c$  that we want to find out.  $P_1$  comes from the original matrix and  $P_1$  is here.  $P_1$  is  $1 \ 2 \ 1$ . Once again, because of the very nature of Eta matrix, it is easy to compute this,  $a \ b$  and  $c$ .

(Refer Slide Time: 18:43)

Handwritten equations on a chalkboard:

$$\begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}$$

$$P_1 = \begin{bmatrix} 4/5 \\ 7/5 \\ 1/5 \end{bmatrix}$$

What we will do now is we will take  $Pbar_1$  equal to 0 into a plus 0 into b plus 5 into c, which is the third equation. 0 into a plus 0 into b plus 5 into c is equal to 1. So, c is 1 by 5. From the first equation, 1 into a plus 0 into b plus 1 into c is equal to 1; so, a plus c is equal to 1. C is 1 by 5, so a is 4 by 5. From the second equation, 0 into a plus 1 into b plus 3 into c is equal to 2. So, b plus 3c is equal to 2; b plus 3 by 5 is equal to 2. So, b is equal to 2 minus 3 by 5, which is 7 by 5.

(Refer Slide Time: 19:47)

$$\begin{array}{rcl}
 3 - \frac{4}{5}\theta \geq 0 & & \frac{15}{4} \\
 4 - \frac{7}{5}\theta \geq 0 & & \frac{20}{7} \checkmark \\
 7 - \frac{1}{5}\theta \geq 0 & & 35
 \end{array}$$

We have now computed  $Pbar_1$  and having computed  $Pbar_1$ , we now have to find out theta, the right hand side values are here. We have to find out the minimum theta, such that 3 minus 4 by 5 theta is greater than or equal to 0; 3 comes from here, 4 by 5 comes from here. So, 3 minus 4 by 5 theta is greater than or equal to 0, 4 minus 7 by 5 theta is greater than or equal to 0 and 7 minus 1 by 5 theta is greater than or equal to 0. This would give us theta is equal to 15 by 4. This would give us theta is equal to 20 by 7 and this would give us theta is equal to 35. Here, theta value is 5 into 3, 15 by 4. So this is 15 by 4. This is 20 by 7 and this is 35. Now, 20 by 7 is the minimum value of theta. So this variable, which is the second variable, will leave the basis. So, this variable is the leaving variable.

We found out that this basis is not optimal, because  $C_1$  minus  $Z_1$  is positive. Variable  $X_1$  enters and when variable  $X_1$  enters, we found out that variable  $X_4$  leaves. We go to the next iteration where the basis changes. From this basis, we know that variable  $X_4$  is leaving and variable  $X_1$  is entering. So, we will have  $X_3$ ,  $X_1$  and  $X_2$  as the set of basic variables.

(Refer Slide Time: 21:42)

$$X_B = \begin{bmatrix} X_3 \\ X_1 \\ X_2 \end{bmatrix} = \begin{bmatrix} 5/7 \\ 20/7 \\ 45/7 \end{bmatrix}$$

The values of these three are given by: the second one was the one which left the basis with theta equal to 20 by 7, so, this variable  $X_1$  will take 20 by 7.

(Refer Slide Time: 22:00)

Revised Simplex Algorithm

$$6X_1 + 8X_2 + X_3 = 10$$
$$X_1 - X_2 + X_4 = 25$$
$$2X_1 + 3X_2 + X_4 = 25$$
$$X_1 + 5X_2 + X_5 = 35$$
$$X_i \geq 0$$
$$X_B = \begin{bmatrix} X_3 \\ X_1 \\ X_2 \end{bmatrix} = \begin{bmatrix} 5/7 \\ 20/7 \\ 45/7 \end{bmatrix}$$

The other two will take the corresponding values. So this will become 3 minus 4 by 5 into theta; so, 3 minus 4 by 5 into 20 by 7 is 16. This would give us 21 by 7 minus 16 by 7 which is 5 by 7 and the third one will be 7 minus 20 by 7 into 1 by 5 which is 7 minus 4 by 7, which is 45 by 7. A quick check again would give us  $X_1$  plus  $X_2$  plus  $X_3$  is equal to 10, 45 plus 20 is 65 plus 5 is 70; 70 divided by 7 is 10.  $2X_1$  plus  $3X_2$  plus  $X_4$  is 0. So this is 25.  $2X_1$  is 40;  $3X_2$  is 135, 175 by 7 is 25 and  $X_1$  plus  $5X_2$  plus  $X_5$ .  $5X_2$  is 225 plus 20 is 245 by 7, which is 35. So this has been checked.

Now, for this set of basic variables, we now need to find out whether this is optimal. To find out whether this is optimal, we have to find out that the  $C_j$  minus  $Z_j$  corresponding to the two non-basic variables, which are  $X_4$  and  $X_5$ .

(Refer Slide Time: 23:50)

Handwritten equations on a chalkboard:

$$C_4 - Z_4$$

$$C_5 - Z_5$$

$$yB_2 = C_B$$

$$yB_1E_2 = C_B$$

$$yE_1E_2 = C_B$$

We have to find out  $C_4$  minus  $Z_4$  and we have to find out  $C_5$  minus  $Z_5$ . Before we do this, we need to find out the value of the dual, which is  $y$ . Dual  $y$  is given by  $yB$  is equal to  $C_B$ . We now call the basis corresponding to this as  $B_2$ ; so  $yB_2$  is equal to  $C_B$ . Now,  $B_2$  will be written as  $B_1$  into  $E_1$ , so  $yB_1E_2$  is equal to  $C_B$  where  $E_2$  is the suitably defined Eta matrix.

(Refer Slide Time: 24:40)

Handwritten matrices on a chalkboard:

$$E_1 = \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix}$$

$$E_2 = \begin{bmatrix} 1 & 4/5 & 0 \\ 0 & 7/5 & 0 \\ 0 & 1/5 & 1 \end{bmatrix}$$

$B_1$  is already known to be  $B_0$  into  $E_1$ , so we will have  $yE_1E_2$  is equal to  $C_B$ . We already have  $E_1$  written here.  $E_1$  is this,  $E_1$  we just copy down for our reference. So,  $E_1$  is  $1\ 0\ 0, 0\ 1\ 0$  and  $1\ 3\ 5$ .  $E_2$  is another Eta matrix with one column, non-identity column. From here, we understand that the second variable is the leaving variable. So the second column in  $E_2$  will be the non-identity column.  $E_2$  will be  $1\ 0\ 0, 0\ 0\ 1$ , which is the third column and the second column is the non-identity column and that second column is given by  $Pbar_1$  which is computed here as  $4$  by  $5, 7$  by  $5$  and  $1$  by  $5$ .

(Refer Slide Time: 25:52)

$$[u_1, u_2, u_3] \begin{bmatrix} 1 & 4/5 & 0 \\ 0 & 7/5 & 0 \\ 0 & 1/5 & 1 \end{bmatrix} = [0 \ 6 \ 8]$$

Now, we know that  $yE_1E_2$  is equal to  $C_B$ . First what we do is we call this  $y$  into  $E_1$  as some  $u$ , so we write  $u$  into  $E_2$  is equal to  $C_B$ .  $u$  is written as  $u_1\ u_2\ u_3$  into  $E_2$  is  $1\ 0\ 0, 4$  by  $5\ 7$  by  $5\ 1$  by  $5, 0\ 0\ 1$  is equal to  $C_B$ .  $C_B$  is the objective function coefficients of the basic variables,  $X_3, X_1, X_2$ ; so,  $0\ 6$  and  $8$ . So, this will be  $0\ 6\ 8$ .

(Refer Slide time: 26:43)

Handwritten work on a chalkboard showing a system of linear equations in augmented matrix form:

$$[u_1, u_2, u_3] \begin{bmatrix} 1 & 4/5 & 0 \\ 0 & 7/5 & 0 \\ 0 & 1/5 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 6 & 8 \end{bmatrix}$$

Below this, the second row is multiplied by 5 to clear the denominator:

$$u \cdot \begin{bmatrix} 0 & 22/7 & 8 \end{bmatrix} \quad \left[ \begin{array}{l} 7u_2 = 6 \cdot 8/5 \\ \phantom{7} \phantom{u_2} = 22/5 \end{array} \right]$$

From this we can find out that  $u_1$  plus  $0u_2$  plus  $0u_3$  is equal to 0. So  $u_1$  is 0, 1 into  $u_1$  plus 0 into  $u_2$  plus 0 into  $u_3$  is 0. From the third, 0 into  $u_1$  plus 0 into  $u_2$  1 into  $u_3$  is 8. So  $u_3$  is 8. From the second one, 4 by  $5u_1$ , 7 by  $5u_2$  plus 1 by  $5u_3$  is equal to 6. So, 7 by  $5u_2$  plus 8 by 5 is equal to 6. 7 by  $5u_2$  is equal to 6 minus 8 by 5; so this is 22 by 5, from which  $u_2$  is 22 by 7. Now, we know this  $u$ . Now, we come back to this and say  $y$  into  $E_1$  is equal to  $u$ .

(Refer Slide Time: 27:47)

Handwritten work on a chalkboard showing the derivation of  $y_1, y_2, y_3$  from the equation  $yE_1 = u$ :

$$[y_1, y_2, y_3] \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix} = \begin{bmatrix} 0 & 22/7 & 8 \end{bmatrix}$$

Below this, the first row is multiplied by 7 to clear the denominator:

$$y \cdot \begin{bmatrix} 0 & 22/7 & -2 \end{bmatrix} \quad \left[ \begin{array}{l} 66 + 5y_3 = 8 \\ 5y_3 = -10 \\ y_3 = -2 \end{array} \right]$$

Finally, the value of  $y_3$  is substituted back into the first row equation to solve for  $y_1$ :

$$y_1 = 8 - 5y_3 = 8 - 5(-2) = 8 + 10 = 18$$

So, you will have  $y_1, y_2, y_3$ , which is  $y$  into  $E_1$ , which is  $1 \ 0 \ 0, 0 \ 1 \ 0, 1 \ 3 \ 5$  which is equal to  $yE_1$ .  $yE_1$  is equal to  $u$ , so this is equal to  $0 \ 22/7$  and  $8$ . From this,  $y$  is equal to 1 into  $y_1$  plus 0 into  $y_2$  plus 0 into  $y_3$  is 0, so  $y_1$  will be 0. 0 into  $y_1$  plus 1 into  $y_2$  plus 0 into  $y_3$  is 22 by 7, so  $22/7$ . 1 into  $y_1$  plus 3 into  $y_2$  plus 5 into  $y_3$  is equal to 8, so  $3y_2$  is 66 by 7 plus  $5y_3$  is equal to 8, so

66 by 7 plus  $5y_3$  is equal to 8. So  $5y_3$  is equal to minus 10 by 7,  $y_3$  is minus 2. So, you have 0, 22 by 7 and minus 2 coming in as the values of the three variables. Having found out  $y$  is 0 22 by 7 and minus 2, with this value of  $y$ , we need to find out the  $C_j$  minus  $Z_j$  of the two non-basic variables  $X_4$  and  $X_5$ .

(Refer Slide Time: 29:45)

The chalkboard shows the following calculations:

$$y = \begin{bmatrix} 0 & \frac{22}{7} & -2 \end{bmatrix}$$

$$C_4 - Z_4 = 0 - yP_4 = 0 - \begin{bmatrix} 0 & \frac{22}{7} & -2 \end{bmatrix} \begin{bmatrix} 6 \\ 0 \\ 1 \end{bmatrix} = 2$$

$$C_5 - Z_5 = 0 - \begin{bmatrix} 0 & \frac{22}{7} & -2 \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} = -2$$

So,  $C_4$  minus  $Z_4$  will be equal to  $C_4$  is 0 minus  $yP_4$ , which is 0 minus 0 22 by 7 minus 2 into  $P_4$ , is from here, which is 0 1 0. This will be minus 22 by 7 and  $C_5$  minus  $Z_5$  is equal to 0 minus 0 22 by 7 minus 2 into 0 0 1 which is plus 2. Now,  $C_5$  minus  $Z_5$  is positive, therefore variable  $X_5$  will enter the basis. This basis is not optimal and variable  $X_5$  will now enter this basis. In order that variable  $X_5$  enters the basis, we need to find out the leaving variable from this.

(Refer Slide Time: 31:13)

In order to find out the leaving variable, we need to find out  $Pbar_5$  which is equal to  $B$  inverse  $P_5$ . Pre-multiplying by  $B$ , we get  $B$  into  $Pbar_5$  is equal to  $P_5$ . This  $B$  is  $B_2$ , so  $B_2$  is equal to  $B_1$  into  $E_2$ .  $B_1$  is  $B_0$  into  $E_1$ , so we will have  $E_1 E_2 Pbar_5$  is equal to  $P_5$ . We already know the values of  $E_1$  and  $E_2$ .  $E_1$  and  $E_2$  are matrices, which are here.

(Refer Slide Time: 32:00)

What we do now is, we simply call this  $E_2$  into  $Pbar_5$  as some  $V$  is equal to  $P_5$ , where this  $V$  is a vector, the some  $V$  equal to  $P_5$ . From this we get  $E_1$  is  $1 \ 0 \ 0, 0 \ 1 \ 0, 1 \ 3 \ 5$  and we could simply call this  $V$  right now as some  $a \ b \ c$  will be equal to  $P_5$ , which is  $0 \ 0 \ 1$ .  $P_5$  is  $0 \ 0, 1$  because in the original problem variable  $X_5$  comes only in constraint number three. Because of the nature of the Eta matrix, it becomes easy to compute  $a \ b$  and  $c$ . From this, we can

easily get  $V$  is equal to the third one is 0 into  $a$  plus 0 into  $b$  plus 5 into  $c$  is equal to 1; so  $c$  is  $1/5$ . Now  $1a$  plus  $0b$  plus  $1c$  equal to 0 would give us,  $a$  equal to minus  $1/5$ .  $0a$  plus  $1b$  plus  $3c$  equal to 0, would give us  $b$  plus  $3c$  equal to 0,  $b$  plus  $3/5$  is equal to 0. So  $b$  is equal to minus  $3/5$ . Once, we know  $V$  is equal to this, we now go back here. We have already written  $E_2$  into  $P_5$  as  $V$ .  $E_2$  is here; so  $1$  into  $1$   $0$   $0$ ,  $4/5$   $7/5$   $1/5$ ,  $0$   $0$   $1$  into  $P_{bar}_5$  is now written as some  $a$   $b$   $c$  is equal to minus  $1/5$  minus  $3/5$  plus  $1/5$ .

(Refer slide Time: 34:14)

$$\begin{bmatrix} 1 & 4/5 & 0 \\ 0 & 7/5 & 0 \\ 0 & 1/5 & 1 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} = \begin{bmatrix} -1/5 \\ -3/5 \\ 1/5 \end{bmatrix}$$

$$P_5 = \begin{bmatrix} 1 & 1/7 & 0 \\ 0 & -3/7 & 2/7 \\ 0 & 0 & 1 \end{bmatrix}$$

Once again by the very nature of the Eta matrix, we can get  $P_{bar}_5$  by simple substitution process as  $0$  into  $a$  plus  $7/5$  into  $b$  plus  $0$  into  $c$ , is minus  $3/5$  from which  $b$  is equal to minus  $3/7$ . This gives us  $7/5b$  is equal to minus  $3/5$ , so  $b$  is equal to minus  $3/7$ . From this,  $a$  plus  $4b$  is equal to minus  $1/5$ .  $a$  minus  $12/35$  is equal to minus  $1/5$ . So,  $a$  minus  $12/35$  is equal to minus  $7/35$ , which is minus  $1/5$ ; therefore take it to the other side,  $a$  will be equal to plus  $5/35$ , which is plus  $1/7$ .

To find out  $c$ ,  $1/5b$  plus  $c$  is equal to  $1/5$ , so  $1/5b$  is minus  $3/35$  plus  $c$ , is equal to  $1/5$  minus  $3/35$  plus  $c$  is equal to  $7/35$ . Taking it to the other side, we get  $10/35$  which is  $2/7$ , so this is  $2/7$ . So, now we have found out  $P_{bar}_5$  and once we know  $P_{bar}_5$ , we can find out theta. The corresponding values are  $5/7$ ,  $20/7$  and  $45/7$ .

(Refer Slide Time: 36:03)

$$\begin{aligned} \left(5 - \frac{1}{7}\right)\theta &\geq 0 \rightarrow \\ \frac{20}{7} + \frac{3}{7}\theta &\geq 0 \\ \frac{45}{7} - \frac{2}{7}\theta &\geq 0 \end{aligned}$$

R E

The corresponding value of theta will be such that, 5 by 7 minus 1 by 7 theta is greater than or equal to 0; from the first one, 5 by 7 minus 1 by 7. 20 by 7 plus 3 by 7 theta greater than or equal to 0, the plus comes because of the minus sign here and 45 by 7 minus 2 by 7 theta greater than or equal to 0. This would give us theta equal to 5. This would give us theta equal to any value, because we have a positive coefficient here and this would give us theta equal to 45 by 2; therefore, this is the variable that leaves. Variable  $X_3$  is the variable that leaves and the basis now changes.

(Refer Slide Time: 37:17)

$$X_B = \begin{bmatrix} X_5 \\ X_1 \\ X_2 \end{bmatrix}, \begin{bmatrix} 5 \\ 5 \\ 5 \end{bmatrix}$$
$$\begin{aligned} \left(5 - \frac{1}{7}\right)\theta &\geq 0 \rightarrow \\ \frac{20}{7} + \frac{3}{7}\theta &\geq 0 \\ \frac{45}{7} - \frac{2}{7}\theta &\geq 0 \end{aligned}$$

The basis now changes to  $X_B$  equal to, we have found out now that the variable  $X_5$  enters the basis and variable  $X_3$  leaves the basis. We have  $X_5$ ,  $X_1$ , and  $X_2$  as the basis and the

corresponding values will be, here this was the variable that left, so this will have theta value which is 5. At theta 5, 20 by 7 plus 15 by 7 is 35 by 7, which is 5 and at theta equal to 5 this will become 45 by 7 minus 10 by 7, which is also 5.

(Refer Slide Time: 38:04)

The chalkboard contains the following handwritten work:

$$X_B = \begin{bmatrix} X_5 \\ X_1 \\ X_2 \end{bmatrix} = \begin{bmatrix} 5 \\ 5 \\ 5 \end{bmatrix}$$

$$X_3, X_4$$

$$y_B = C_B$$

$$y_{E_1 E_2 E_3} = C_B$$

$$\frac{5}{7} - \theta \geq 0 \rightarrow$$

$$\frac{20}{7} + \frac{3\theta}{7} \geq 0$$

$$\frac{45}{7} - \frac{2\theta}{7} \geq 0$$

$$C_1 - Z_1 = 6 - [0$$

$$= 6 - 8/5$$

$$C_5 - Z_5 = 0 - [0$$

$$\bar{P}_1 = B^{-1} P_1$$

$$B \bar{P}_1 = P_1$$

$$E_1 P_1 = P_1$$

$$\begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix} \begin{bmatrix} 2 \\ 6 \\ 5 \end{bmatrix}$$

$$P_1 = \begin{bmatrix} 4/5 \\ 7/5 \end{bmatrix}$$

We now have another basic feasible solution with  $X_1$  equal to 5,  $X_2$  equal to 5 and  $X_5$  equal to 5. Once again we need to check whether this basis is optimal and in order to do that, we have to find out  $C_j$  minus  $Z_j$  corresponding to the two non-basic variables which are  $X_3$  and  $X_4$  and before we find out  $C_3$  minus  $Z_3$  or  $C_4$  minus  $Z_4$ , we need to find out  $y$ , which is the value of the dual, so  $y_B$  is equal to  $C_B$ . Now, this  $B$  is called  $B_3$ . So  $B_3$  will be  $B_2$  into  $E_3$ .  $B_2$  is  $B_1$  into  $E_2$ .  $B_1$  is  $B_0$  into  $E_1$  and  $B_0$  is  $I$ . So putting all of them together, we will get  $y$  into  $E_1 E_2 E_3$  is equal to  $C_B$ . We right now have values of  $E_1$  and  $E_2$ , which are written here. So, we need to write the value of  $E_3$ .  $E_3$  is another Eta matrix, which is an identity matrix, with one column not being an identity column. From this we found out that the first variable actually left the basis, therefore the first column is a non-identity column.

(Refer Slide Time: 39:38)

The other two columns will be 0 1 0, 0 0 1 and the first column will be corresponding to  $P_{bar}_5$ , which we found out as 1 by 7, minus 3 by 7, and 2 by 7. Because we wrote this out of  $P_{bar}_5$ , so if  $P_{bar}_5$  is 1 by 7, minus 3 by 7, 2 by 7, we would have got 5 minus 1 by 7 theta, 20 by 7 plus 3 by 7 theta 2 by 7 theta. So this is our  $E_3$ .

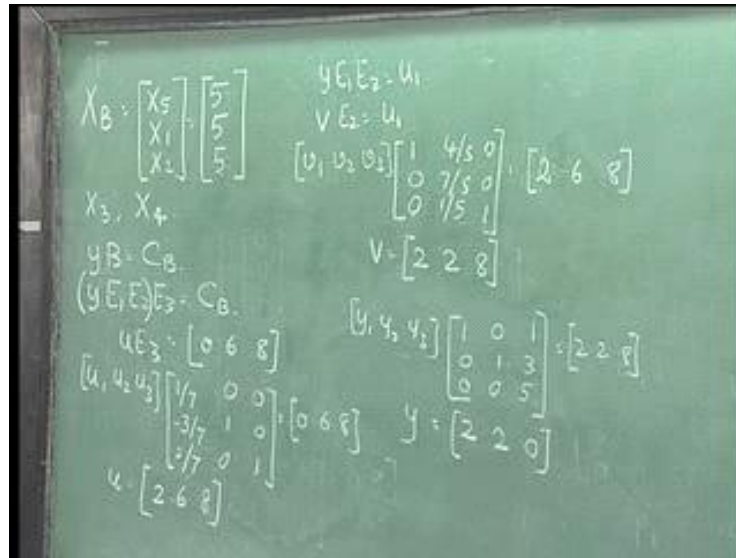

(Refer Slide Time: 40:34)

Now using this  $E_1, E_2, E_3$  and  $C_B$ , we should now find out  $y$ . What we first do is we call this whole thing as  $u$  and say  $u$  into  $E_3$  is  $C_B$ .  $C_B$  is the objective function coefficient of the basic variables, which is 0 6 8, so this is 0 6 8. We now substitute  $E_3$ . So,  $u_1 u_2 u_3$  into 1 by 7 minus 3 by 7 2 by 7, 0 1 0, 0 0 1 is equal to 0 6 8. Now from the third one 0 into  $u_1$  plus 0 into  $u_2$  plus 1 into  $u_3$  is 8. So  $u_3$  is 8. 0 into  $u_1$  plus 1 into  $u_2$  plus 0 into  $u_3$  is equal to 6, so  $u_2$  is 6. 1

by  $7u_1$  minus 3 by  $7u_2$  plus 2 by  $7u_3$  is equal to 0. So, 1 by  $7u_1$  plus, minus 18 by 7 plus 16 by 7 is equal to 0. So, 1 by  $7u_1$  minus 2 by 7 is equal to 0. 1 by  $7u_1$ , this is minus 18 by 7 plus 16 by 7, so minus 2 by 7. 1 by  $7u_1$  minus 2 by 7 is equal to 0, from which  $u_1$  is equal to 2. Once we know  $u_1$  is equal to 2, we now go back and find out the other one.

(Refer Slide Time: 42:32)

This is called  $u_1$ . So  $yE_1E_2$  is equal to  $u_1$ , so we now call this as  $VE_2$  is equal to  $u_1$ . So,  $V$  will be  $v_1, v_2, v_3$  into  $E_2$  is 1 0 0, 4 by 5 7 by 5 1 by 5, 0 0 1 is equal to 2 6 8, because we found out that  $u$  is 2 6 8. Once again, by the very nature of Eta matrix we can get  $V$  is equal to  $v_1$  plus  $0v_2$  plus  $0v_3$  is equal to 2, from which  $v_1$  is 2. Again  $0v_1$  plus  $0v_2$  plus  $1v_3$  is 8, so we get 8.

Second one is, 4 by  $5v_1$ , which is 8 by 5 plus 7 by  $5v_2$  plus another 8 by 5. 1 by 5 into 8 is 8 by 5 which is equal to 6; so 8 by 5 plus 8 by 5 is 16 by 5. So 6 minus 16 by 5 is 14 by 5. So 7 by  $5v_2$  is equal to 14 by 5 therefore,  $v_2$  is 2.

Now we have found  $V$ . We again go back, we have written  $y$  into  $v_1$  as  $V$ . So, we write  $y_1, y_2, y_3$  into  $E_1$ , which is from here 1 0 0, 0 1 0, 1 3 5 is equal to 2 2 8 from which  $y$  is equal to, once again by the very nature of Eta matrix,  $y_1$  plus  $0y_2$  plus  $0y_3$  is 2; so  $y_1$  is 2.  $0y_1$  plus  $1y_2$  plus  $0y_3$  is 2, so  $y_2$  is 2. This alone is  $y_1$  plus  $3y_2$  plus  $5y_3$  is 8.  $y_1$  is 2,  $3y_2$  is 6, 6 plus 2 is 8,  $y_3$  therefore is 0. 2 2 and 0 is the value of  $y$  and we can actually even verify the value of  $y$  from here. We also know that at any point the value of the objective function of the primal and the dual are the same. So primal has  $X_1$  equal to 5,  $X_2$  equal to 5; substituting, this is 30 plus 40 is 70 and the other dual is 2 2 and 0; 2 2 and 0 would give us the same 70. This is another

verification that the dual that we computed is correct. Once we know that this is the value of the dual, we now go back and there are two non-basic variables  $X_3$  and  $X_4$ .

(Refer Slide Time: 45:57)

The image shows handwritten mathematical work on a chalkboard. At the top, it shows the calculation of dual variables  $y_1, y_2, y_3$  from a system of equations:
$$[y_1, y_2, y_3] \begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 3 \\ 0 & 0 & 5 \end{bmatrix} = [2 \ 2 \ 0]$$
Below this, the dual variables are found to be  $y = [2 \ 2 \ 0]$ . Then, the reduced costs for non-basic variables  $X_3$  and  $X_4$  are calculated:
$$C_3 - Z_3 = 0 - [2 \ 2 \ 0] \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} = -2$$

$$C_4 - Z_4 = 0 - [2 \ 2 \ 0] \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} = -2$$

We need to find out  $C_3$  minus  $Z_3$ , which is 0 minus  $y$  which is 2 2 0 into  $P_3$  which is 1 0 0, and that is minus 2. Now,  $y$  is 2 2 0,  $y$  into  $P_3$ .  $P_3$  comes from here, corresponding to variable  $X_3$ . So here the coefficient is 1 0 and 0. Similarly  $P_4$  will be 0 1 and 0, because this does not appear in the first equation. So  $C_4$  minus  $Z_4$  is equal to 0 minus 2 2 0 into 0 1 0 which is minus 2. So,  $C_j$  minus  $Z_j$  corresponding to both the non-basic variables are negative. There is no entering variable and the algorithm terminates. The algorithm terminates now with the objective function value of 70 with  $X_1$  equal to 5,  $X_2$  equal to 5,  $Z$  is equal to 70 and from the dual  $y_1$  is equal to 2,  $y_2$  is equal to 2 and  $y_3$  equal to 0; so, 20 plus 50 is also 70. The algorithm terminates.

This is how the revised simplex algorithm works. On the face of it, it looks much more computationally intensive or laborious compared to the tabular form. Tabular form is much more comfortable, largely because we are used to a tabular form. Now, the only change that actually happened between the tabular form and this way of doing it, is the fact that  $B$  inverse was not explicitly computed either using the determinant cofactor adjoint method or by using Gauss Jordan, which we did in the tabular form.

If we look at this very carefully, in this iteration to find out  $y$  we had something like  $y$  into  $E_1$  into  $E_2$  into  $E_3$  equal to  $C_B$ , which means, we have to do this three times to get  $y$ . In case this was not optimal, then to find out the entering variable  $P_{bar}$  we need to again do it three times.

In the third iteration it will be three multiplication to get  $y$  and perhaps another three multiplication to get the  $Pbar$ , which means, in the hundredth iteration, we will be multiplying it hundred times in the forward direction to get  $y$  and another hundred times in the reverse direction to get a  $Pbar$ . Therefore, the question naturally arises is, is this a very efficient method?

Thus, apart from this, everything else was the same and more importantly we also need to store the  $E_1$ ,  $E_2$  and  $E_3$ . We do not need to store any other thing; we will be storing this. But in addition to that, we only need to store  $E_1$ ,  $E_2$  and  $E_3$ . From a storage point of view, it is said that we normally want to store it as 3 into 3 matrix.  $E_1$  will be stored only as this vector 1 3 5 and a simple identification that this vector is in the third column. This one will be stored as 4 by 5 7 by 5 1 by 5 and 2, which means, this first three are in second column and so on. You do not end up storing a large matrix, instead you store only a vector; you need to store only the vector for every  $E$ .

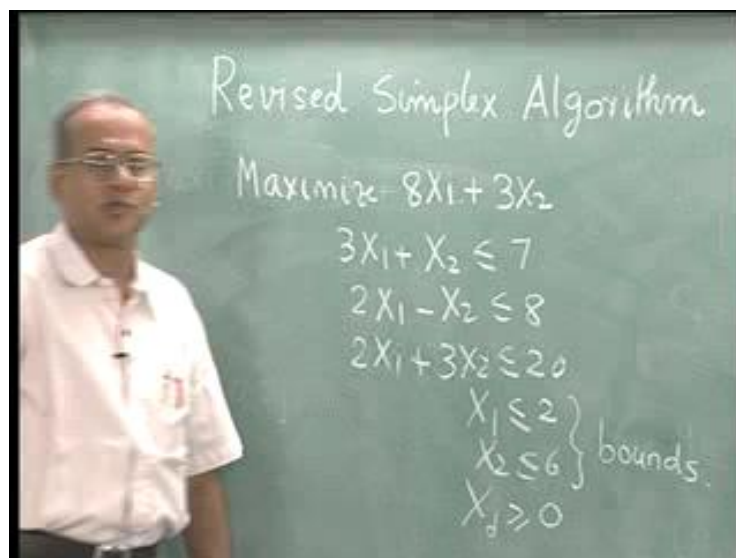

The other question is this laborious process of forward multiplications and reverse multiplications efficient? Incidentally, the answer is yes. For the normally small sized problems that we worked out, we know that the tabular form is much better than this. But as the problem size increases, say we have linear programming problems with 100 constraints or more then, we realize that actually this way of calculating  $y$  and  $Pbar$  in forward and backward directions is actually much faster. For the simple problems like 2 by 2, 3 by 3 that we normally encounter in a classroom, the tabular method is still very efficient. The moment we get into solving large sized linear programming problems typically more than 100 constraints, this method is found to work much better than the tabular.

In terms of speed, this method is much better and one of the things with which we started this course is to find out how do we make the simplex work a little faster. So we zeroed in on the fact that the most important thing in the simplex is actually the matrix inversion. If we do the matrix inversion, well, by a better method and do it faster automatically, time taken per iteration will come down. The number of iteration, we have already said, we could do based on the largest coefficient rule or any suitable rule. The revised simplex method helps in actually bringing down the computation of this simplex algorithm, because the time taken per iteration comes down, when the problem size is large. But the method that we have seen particularly to invert is called the Eta factorisation of the basis, which we have seen to convert the basis as a product of several Eta matrices and we also use this method called

product form of the inverse where to find out the inverse, we try and multiply these Eta matrices once in the forward direction and once in the reverse direction; forward direction to get  $y$  and in the reverse direction to get Eta. This is the brief description of the revised simplex algorithm through a numerical illustration.

The next thing that we like to see in linear programming is another important aspect of linear programming. Now, in the next important aspect of linear programming, we also wish to see how well we can actually make the linear programming problem work, if constraints in linear programming are of a certain type. We take a simple example. To start the example what we will do is maximize  $8X_1$  plus  $3X_2$ , subject to  $3X_1$  plus  $X_2$  less than or equal to 7,  $2X_1$  minus  $X_2$  less than or equal to 8,  $2X_1$  plus  $3X_2$  less than or equal to 20;  $X_1$  less than or equal to 2,  $X_2$  less than or equal to 6,  $X_j$  greater than or equal to 0.

(Refer Slide Time: 52:53)

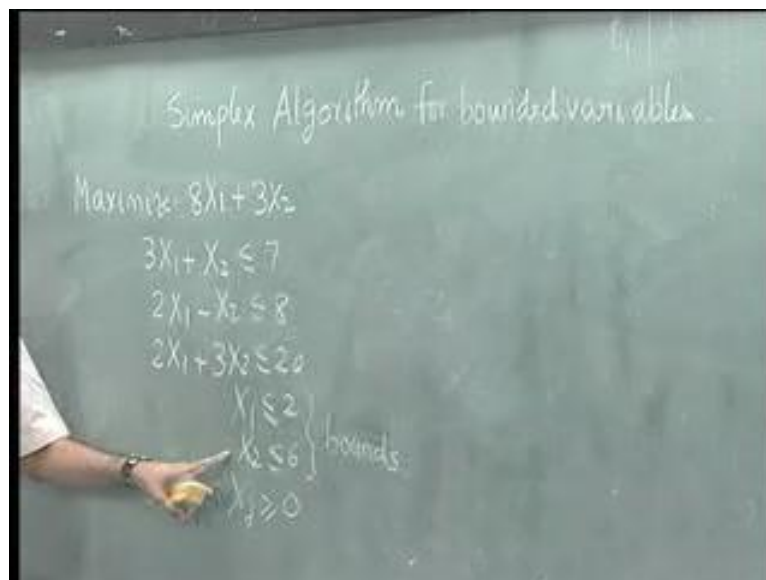

So, let us consider a linear programming problem of this type. Right now, this linear programming problem has two variables  $X_1$  and  $X_2$  and it appears that this linear programming problem has five constraints, three constraints involving both  $X_1$  and  $X_2$ ,  $3X_1$  plus  $X_2$  less than or equal to 7 and so on. The last two are constraints of the type  $X_1$  less than or equal to 2 and  $X_2$  less than or equal to 6. Now, this problem can be solved using the revised simplex that we just now saw in this lecture. The thing is if we use the revised simplex or even the tabular form of the simplex, we will have five constraints and in every stage or every iteration, we will be inverting a 5 by 5 matrix.

A much closer look at these two constraints would tell us that these constraints involve only one variable and therefore these constraints are not treated as constraints, they are called bounds on the variable. Now, the question is do we have to look at this as 5 by 5 problem and solve or can we simply take these bounds outside, look at it only as a three constraint problem and then at every stage suitably incorporate or bring these bounds back into the solution. If we end up doing that, then we have reduced the number of constraints. We already saw in this lecture that the biggest aspect of an iteration of simplex is the matrix inversion.

If we do not treat this as a bound and treat it separately, we end up having five constraints and we end up inverting a 5 into 5 matrix in every iteration. Whereas, if we pull these two things out and solve the resultant three constraint problem also making sure that, these are satisfied, but solving it as a 3 constraint problem, then we end up having a 3 by 3 matrix to invert in every iteration. So, can simplex be modified in such a manner that if there are bounds, these bounds are not treated as constraints, these bounds are taken separately and only the resultant constraints are solved; which also means that a constraint is a constraint, when it involves more than one variable. If it involves only one variable, then the constraint becomes a bound. So can simplex be adapted to problems, which has bounded variables.

(Refer Slide Time: 56:30)

We will now address what to do with simplex, particularly when simplex has bounded variables and therefore the algorithm that we will see is called simplex algorithm for bounded variables. As I said, these two are the bounded variables. We will simply take these variables outside, treat them as bounds, write them separately as  $X_1$  less than or equal to 2 and  $X_2$  less

than or equal to 6. Now, this bounded method can be solved using the reverse simplex algorithm. We can also solve it by the normal algebraic method, with the motivation to simplex; not the typical algebraic method, where we evaluate all the basic solutions, but we can solve it by the algebraic method. How we do the simplex method for bounded variables in using the algebraic method, we will see in the next class.
