Steam and Gas Turbines: H-S Plots and Velocity Triangle.

Good afternoon, I welcome you to this discussion on steam and gas turbine. This is essentially the continuation of what we have discussed in the last class. In the last class as you can recollect that we have doubt about the construction of the steam and gas turbines, in particular the steam turbines and now we will talk about their performance. So to understand this we will take resort to the velocity triangles that we have already discussed in the earlier part of this module and then we will apply it for the case of steam turbines, of course you have to keep in mind what I talked about in the last class that we are talking about the steam as a superheated steam and not really talking about the wet phase.

(Refer Slide Time: 1:08)

FLUID DYNAMICS AND TURBOMACHINES
PART D: Module 02—Steam and Gas Turbines

Nozzle Efficiency:

$h_{03} = h_{02}$ Why?

What about P_{03} and P_{02} ?

Nozzle efficiency, η_N

$$\eta_N = \frac{\frac{C_2^2}{2}}{\frac{C_{2s}^2}{2}} = \frac{C_2^2}{2\Delta h_{isen}}$$

Alternately, it can be expressed in terms of Loss Coefficient (ζ_N) and Velocity Coefficient (K_N)

$$\zeta_N = \frac{h_2 - h_{2s}}{\frac{C_2^2}{2}} \quad K_N = \frac{C_2}{C_{2s}} \quad \Rightarrow \quad \eta_N = K_N^2 = \frac{1}{1 + \zeta_N}$$

So we will talk about the HS plots and connect the 2 and most importantly we will talk about the degree of reaction or the reaction ratio. Now we will define few terminologies which will help us to also understand these turbines and solve the problem that we have given in the tutorial. The 1st is the nozzle efficiency. We have already talked about that the nozzle has a higher pressure, higher enthalpy at the inlet and after the expansion, the enthalpy and the pressure should drop.

And if we collect our terminology, we have said higher the value of pressure enthalpy, we will give a higher number. So in this case if you remember the simple impulse turbine for example, we have first the nozzle and then the rotor. So if I start from the rotor exit as 1, then rotor inlet becomes 2 which is also nothing but the nozzle exit. So the nozzle inlet should have a number 3. So please note that these numbers 3, 2 may differ in different books but we are following the unified notation that we have discussed towards the beginning of these lectures on Turbo machines.

So 3 to 2 is an expansion process and 3 to 2S is an idealised process where 2S refers to the isentropic expansion. P_{03} corresponds to the total pressure, P_{02} corresponds to the total pressure and P_3 corresponds to the stagnation state. And P_2 corresponds to the stagnation state at the exit of the nozzle. The corresponding pressure, please note is P_{02} . In the last lecture on compressible flows, this aspect we have already discussed. We have shown that H_{03} should be equal to H_{02} , why is that? You recollect that nozzle does no work and there is no heat transfer, so from the 1st law of thermodynamics, neglecting potential energy changes, we can say that H_{03} is equal to H_{02} .

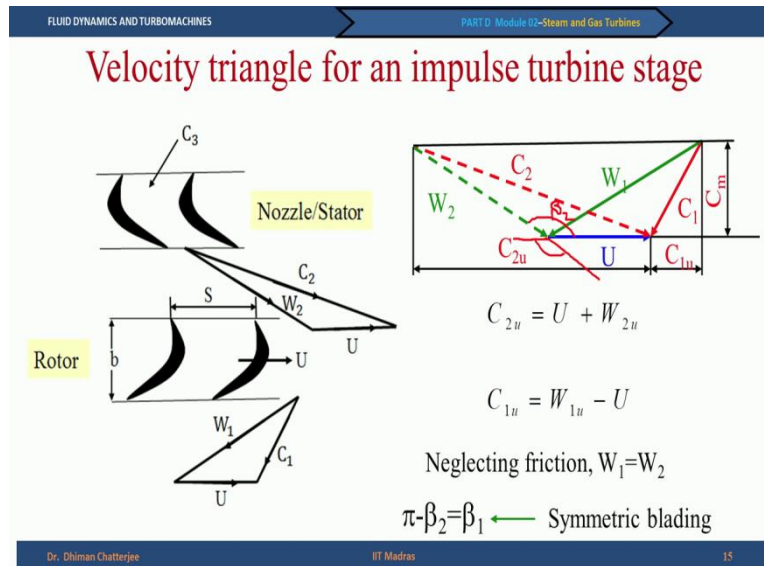

But what about pressure? That also we have discussed in the last lecture that P_{03} is not equal to P_{02} and there is a pressure drop to overcome the friction. So this is depicted here. And that brings to us the concept of nozzle efficiency and we can say that nozzle efficiency η_N is given as C_2^2 square by 2 divided by C_{2S}^2 square by 2. What we are essentially saying is this velocity, that is which takes from here to here as a actual velocity that is obtained that the exit of the nozzle to the ideal velocity that you can get from the exit of the nozzle.

And of course we know that ideal velocity is obtained if you say that from the isentropic expansion and $\Delta H_{\text{isentropic}}$ or ΔH_{isen} refers to the total drop in enthalpy from the State 03 to 2S. So η_N then can be represented as C_2^2 square by C_{2S}^2 square or C_2^2 square by 2 ΔH_{isen} . Alternately it can also be expressed in terms of loss coefficient ζ_N or velocity coefficient, the nozzle velocity coefficient for example we have discussed also in case of Pelton turbine. So we can say ζ_N is nothing but H_2 minus H_{2S} , the loss in enthalpy divided by C_2^2 square, the what fraction of it is lost. And then we can also define the velocity coefficient as C_2 by C_{2S} .

If you manipulate with these terms and I would ask you to do it yourself, to show that that η_N is equal to K_N square, of course this is obvious, is equal to $1 / (1 + \zeta_N)$.

So η_N equal to $K N^2$ equal to $1 / (1 + \zeta_N)$. And this is, this is a way of expressing the nozzle efficiency.

(Refer Slide Time: 5:32)

So let us look at the velocity triangles for an impulse turbine stage. So this is an impulse turbine stage and we are talking about the velocity triangle. So the velocity that enters here is C_3 , which is at the inlet of the nozzle, leaves with an absolute velocity C_2 , you see that C_3 has increased by several orders, which is expected because nozzle is supposed to increase it. Then you know the pressure and the suction surfaces, we can get the direction of rotation as shown here, we can construct the velocity triangle at the inlet of the rotor and similarly at the exit of the rotor.

And you can also once again verify that had there been no blade, rotor blade, the velocity would have continued in the direction of W_2 but now it is forced to go in W_1 and hence the deflection angle is large. So let us draw the velocity triangles together. When we talk about axial flow turbines, many times what we do, we take advantage of the fact that this blade velocity, Blade peripheral velocity U is same as the rotor inlet and outlet. And we can draw it in terms of common base.

So this U serves as a common base and the direct method of comparing the inlet and outlet velocity triangles. We can mark C_{2u} and C_{1u} and please note that we have earlier written when we talked about Euler's energy equation or Euler's turbine equation that it is C_{2u} minus C_{1u} but that is because they were on the same side. Now if you look at this graphical

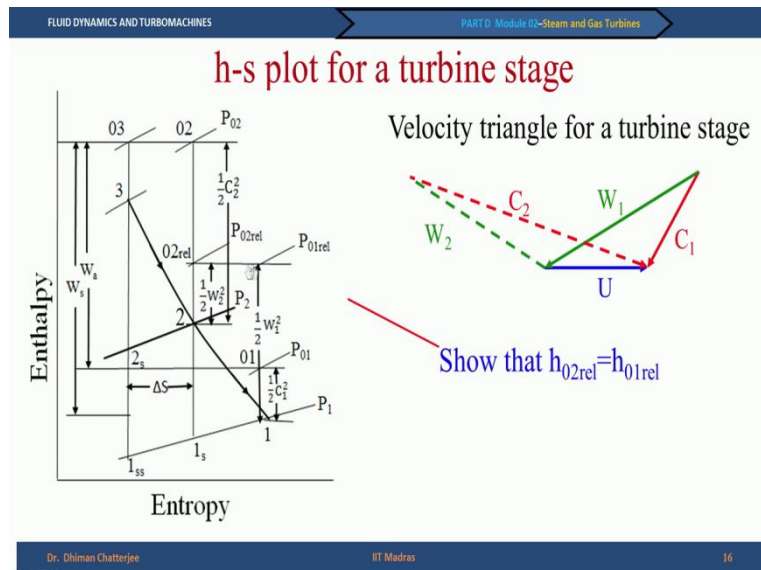

representation, you can see that $C2U$ is on one side and $C1U$ is on the other side. So what we are essentially trying to do is find out the distance between this tip and the other one.

So we are essentially trying to talk about the summation of the total distance $C2U$ and $C1U$. So in case they are on the same side, then what will happen is it is going to be $C2U$ minus $C1U$, in this case it will be $C2U$ minus of minus $C1U$, because $C1U$ is on the opposite side. This has to be borne in mind when we follow this discussion today. So let us look at it. We are talking about $C2U$ as U plus $W2U$ and $C1U$ is $W1U$ minus U and hence neglecting friction where we can consider the $W1$ equal to $W2$, the same as we have done in case of Pelton turbine, we can find out that $\pi - \beta_2 = \beta_1$, I will come back to this point again.

And this is known as symmetric blading. Please note the relationship that $\pi - \beta_2 = \beta_1$. This is valid because of the nomenclature that we have used, the sign convention of β we have used. You can get a similar symmetric blading condition in other way if you use some other way of denoting the blade angles. But for the way we have denoted the blade angles, that is blade angle in our case is denoted by the angle between the positive direction of W for example let us say I am talking about positive direction of W and the negative direction of U which is this angle.

So this angle is my β which means the vertically opposite angle, this also should be my β . So this should be my β_2 . So please note that this is the sign convention we have used and hence because of the sign convention, the symmetric blade condition gives me $\pi - \beta_2 = \beta_1$. If you had followed, I repeat, if you had followed any other convention of the blade angles, then this relationship will be changed but still you should get the symmetric blading because that is important because velocity triangles here we are talking about is the same, the angle representation is different.

(Refer Slide Time: 9:56)

So we can look at the HS plot for a turbine stage, so 3 to 2 is an expansion in the nozzle, 2 to 1 is the expansion in the rotor. And we are talking about 3 to 2S as the isentropic expansion in the nozzle and 2 to 1S is the isentropic expansion in the rotor and 1 SS talks about the isentropic expansion from 3 at the pressure P_3 to the pressure P_1 . We can also write that this is P_{02} and this line corresponds to P_03 , so H_{03} should be equal to H_{02} as we have discussed and then this distance is the velocity rise which is half C_2 square.

We can also show that this pressure is called P_{02} relative. Please note the distinction between P_{02} and P_{02} relative. When I say P_{02} , I mean P_2 plus half, basically it is connected with the 2 square, we cannot write with half ρC_2 square, I am sorry, we cannot write it but we have to connect it with C_2 square. For example, I can write the T_{02} is equal to T_2 plus C_2 square by $2C_p$ and we can connect the pressure also using the relationship we have derived earlier in terms of Mach number.

Now P_{02} relative is connected with the velocity of W_2 instead of W_2 . Similarly P_{01} relative is connected with the velocity W_1 , relative velocity W_1 instead of C_1 . Whereas P_{01} is with the, connected with the absolute velocity C_1 . So let us look at it again. P_1 and P_{01} is connected with the absolute velocity at the exit of the rotor C_1 . P_{01} relative is the stagnation pressure based on the relative velocity condition and that is given, related with W_1 square. Similarly with P_{02} and P_{02} relative.

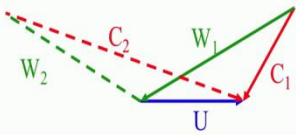

So now velocity triangle for a turbine stage, if I look at the velocity triangle for the turbine stage which we have already drawn in the last time, we can get that H_{02} relative equal to H_{01}

relative. I am not showing in today's lecture, I will give a separate handout but I suggest that you 1st derive it yourself. If you are really not in a position to do it, then you look at the handout and then we can have the discretion if required. But please try to prove that for the condition given H02 relative equal to H01 relative, I have already shown it of course by this horizontal line.

(Refer Slide Time: 12:54)

FLUID DYNAMICS AND TURBOMACHINES PART D: Module 02—Steam and Gas Turbines

Some definition $C_{2u} - (-C_{1u})$

Blade Efficiency (η_{bl}):

$$\eta_{bl} = \frac{W_{bl}}{C_2^2/2} = \frac{2U [C_{2u} + C_{1u}]}{C_2^2}$$

Normal Stage: Absolute velocities and flow angles in stator at the entry and exit of the stage are identical. $C_3=C_1$ and $\alpha_3=\alpha_1$.

Total-to-total efficiency (η_{tt}): $\eta_{t-t} = \frac{h_{03} - h_{01}}{h_{03} - h_{01ss}}$

Similar to nozzle loss coefficient (ζ_N), we can define rotor loss coefficient (ζ_R).

$$\zeta_N = \frac{h_2 - h_{2s}}{C_2^2/2} \quad \zeta_R = \frac{h_1 - h_{1s}}{W_1^2/2}$$

Dr. Dhiman Chatterjee IIT Madras 17

So some more definitions we need, we can talk about the blade efficiency η_{bl} as W_{bl} by C_2^2 square by 2. What it is saying that how much specific work is obtained from the blade when the kinetic energy input is C_2^2 square. So that means how much of the kinetic energy that is being converted into useful blade specific work. And this is exactly the same but we have talked about in case of Pelton turbine. Please keep the similarity between the Pelton turbine definitions and the steam turbine, exact expressions will little bit vary but the philosophy is same.

In case of Pelton turbine we talked about the jet velocity C_j which is our C_2 , which comes out with a high kinetic energy. In this case the scheme comes out of the nozzle with C_2 square by 2 as the kinetic energy per unit mass. So we can write now $2U C_{2u}$ plus C_{1u} . I again reemphasise this point that you can think about this C_{2u} plus C_{1u} in this way. You can say that C_{2u} minus of minus C_{1u} , so this is what I am saying. C_{2u} minus of minus C_{1u} , this 2nd minus inside the bracket actually denotes that C_{1u} is in the direction opposite to C_{2u} and we are talking about the distance, total distance in the graphical scheme.

So we can say that $C2U$ plus $C1U$ by $C2$ square. Again to remind you we are talking about this distance of that from this part, from this tip of U we are going in the left side to get $C2U$ and we are going on the right side to get $C1U$ and has the total distance is $C2U$ plus $C1U$. This has to be borne in mind. And we should not use just $C2U$ minus $C1U$ without having the velocity triangle. In fact let me also stress at this point that whenever you are solving problems where we need to find out velocity or the blade angles, it is always a good habit to draw the velocity triangle as accurately as you can and then work it out. That will always give the confidence that your values are becoming realistic.

So next definition that we need to know is the normal stage definition. See we are talking about multiple stages of a steam or gasturbine, so in this case the normal stage is one in which the absolute velocities and flow angles in stator at the entry and exit of the stage are identical. That is C_3 is equal to C_1 and $\text{Alpha } 3$ is equal to $\text{Alpha } 1$. Why do we need such a normal stage definition? That is because the flow that leaves from one stage actually goes to the next stage. So if we are trying to talk about the similar constructions, then we are saying that C_3 is equal to C_1 and $\text{Alpha } 3$ is equal to $\text{Alpha } 1$.

So unless otherwise mentioned, we can always assume that this is normal stage assumption is valid. The next thing is our total to total efficiency. We have talked about the total to total efficiency earlier also and we have told that time that total to total efficiency is nothing but H_{03} minus H_{01} divided by $H_{03} - H_{01}$ SS. Please recollect that H_{03} minus H_{01} SS is isentropic enthalpy, isentropic process by which the enthalpy drop is calculated and then H_{03} minus H_{01} is the actual process. Similar to nozzle loss coefficient ζ_N , we can also define rotor loss coefficient ζ_R as follows. We can say that if ζ_N is nothing but H_2 minus H_{2S} by C_2 square by 2, then ζ_R will be H_1 minus H_{1S} .

H_1 minus H_{1S} is actually reflecting how much of the enthalpy is lost and then divided by the corresponding velocity, in case the rotary rotating, so we can talk in terms of the relative velocity W_1 square by 2 which comes out of the rotor exit.

(Refer Slide Time: 17:31)

FLUID DYNAMICS AND TURBOMACHINES PART D: Module 02- Steam and Gas Turbines

If we further assume $C_{1ss} \approx C_1$ we can show

$$\eta_{t-t} = \left[1 + \frac{\zeta_R W_1^2 + \zeta_N C_2^2 \left(\frac{T_1}{T_2} \right)}{2(h_3 - h_1)} \right]^{-1} \quad \leftarrow \text{Prove this}$$

Hints: 1) Use the relation: $\left(\frac{\partial h}{\partial s} \right)_p = T$

↓

$$h_{1s} - h_{1ss} = T_1 (s_{1s} - s_{1ss})$$

$$h_2 - h_{2s} = T_2 (s_2 - s_{2s})$$

Dr. Dhiman Chatterjee IIT Madras 18

And if we further assume that C1 SS is almost equal to C1, you know that they are not exactly same. Why, because densities are not same and if you have to say the same mass flow rate as we have discussed earlier, then C1 SS is not equal to C1.

But if we assume that the variation between C1 SS and C1, the difference between C1 SS and C1 is not significant, then we can say that Eta TT is can be given as 1+ zeta R times W1 square plus zeta N times C2 square multiplied by T1 by T2, whole divided by 2 H3 minus H1 to the power -1. You can prove this, I will also leave this in the handout but you try do it yourself and I am giving you a few hints. You can use the relationship that Dell H Dell S at constant pressure is T and then using that relationship you can write that H1 S minus H1 SS is equal to T1 times S1 S minus S1 SS and H2 minus H 2 S is T2 times S2 to minus S2S.

That is coming directly from this relationship. And once you use the definitions of zeta R, zeta N, you should be able to get an expression of efficiency, total total efficiency in terms of zeta R and zeta N. And as you can see that this relationship will require little bit of manipulation of the expressions you have given, so I will leave it for you to prove it, I will also give you handout which you can refer, I would suggest only if you are not able to do it yourself. Try it out, I hope you will be able to derive it.

(Refer Slide Time: 19:24)

FLUID DYNAMICS AND TURBOMACHINES PART D: Module 02- Steam and Gas Turbines

Degree of reaction (Reaction Ratio) of a turbine stage

$$R = \frac{h_2 - h_1}{h_3 - h_1} \quad \text{For a normal stage: } C_3 = C_1 \quad \Rightarrow \quad R = \frac{h_2 - h_1}{h_{03} - h_{01}}$$

$$R = \frac{h_2 - h_1}{h_{02} - h_{01}} \quad \text{as } h_{03} = h_{02}$$

$$h_{02rel} = h_{01rel} \quad \Rightarrow \quad h_2 - h_1 = \frac{1}{2}(W_1^2 - W_2^2)$$

$$W_{bl} = U(C_{2u} + C_{1u}) = h_{03} - h_{01} = h_{02} - h_{01}$$

$$R = \frac{W_1^2 - W_2^2}{2U(C_{2u} + C_{1u})}$$

If $C_{1m} = C_{2m} \quad W_1^2 - W_2^2 = (W_{1u} - W_{2u})(C_{1u} + C_{2u})$

$$R = \frac{W_{1u} - W_{2u}}{2U}$$

Dr. Dhiman Chatterjee IIT Madras 19

So the next thing that we have to talk about is degree of reaction or sometimes called reaction ratio in different textbooks and literature of a turbine stage. We know that R equal to degree of reaction is equal to H2 minus H1 divided by H3 minus H1. And for a normal stage, we know that C3 equal to C1, just now we have talked about it, so we can add in the, all the terms, the C3 and the C1 respectively and then we can write that R equal to H2 minus H1 whole divided by H03 minus H01. What we have done, we have written H03 as H3 plus C3 square by 2. And H1 as, H01 as H1 plus C1 square by 2. And since C3 and C1 are same so H3 minus H1 is equal to H03 minus H01.

And we can write R equal to H2 minus H1 by H0 2 minus H01. How can we write it, because H03 is equal to H02. We have already shown that in the nozzle the stagnation enthalpy remains constant. We also know that H0 2 relative is H01 relative, I am giving it in red to remind you that you have to prove it and then we get that H2 minus H1 is half W1 square minus W2 square. That is I can write H0 2 relative as H2 plus half W2 square and H1 plus half W1 square will give me H0 1 relative.

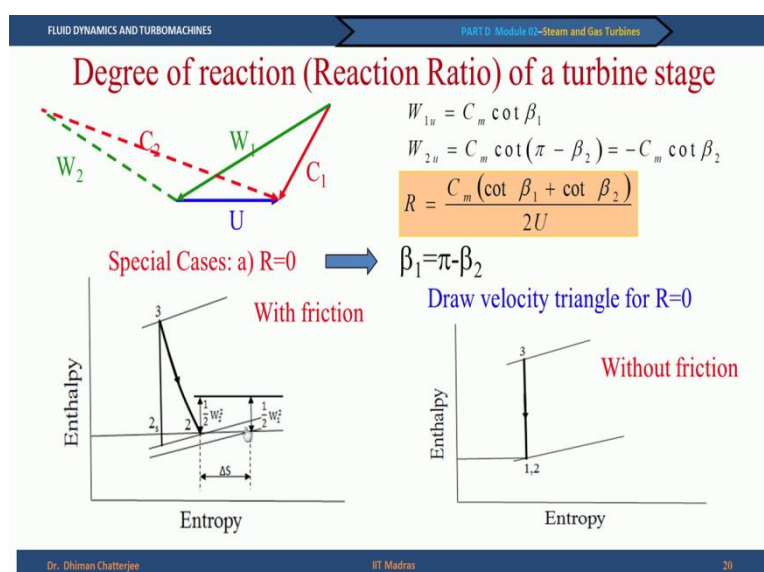

If I write the H2 minus H1, because that is in the numerator in terms of the velocity differences or the kinetic energy differences, then H2 minus H1 can be related with W1 and W2. So we can also know that W B L is U times C2U plus C1U which gives me H0 3 minus H01. And which is nothing but H0 2 minus H0 1. So now we have an expression for H0 2 minus H0 1 as well as H2 minus H1 in terms of velocity components. And we can write in either way R, that is in terms of the enthalpies or in terms of the velocities.

And we can write that $W_1^2 - W_2^2 = 2U(C_2U + C_1U)$. Let us look at the velocity triangle once again and we can say that if $C_1 = C_2$, if you make this further assumption, then we should be able to say that $W_1^2 - W_2^2$ can be written as $W_1U - W_2U$ multiplied by $C_1U + C_2U$. How do you get it? Let us look at how you get this. You can write for example $W_2^2 = C_1^2 + W_{2U}^2$. And $W_1^2 = C_2^2 + W_{1U}^2$ because I was assumed that $C_1 = C_2$ plus W_{1U}^2 .

So if you subtract it out, what do you get it is $W_1^2 - W_2^2 = W_1U + W_2U$ multiplied by $W_1U - W_2U$. So now what happens is, this is what we obtained, so what happens is now $W_1U - W_2U$ is nothing but we are talking about this distance. We are talking about this distance which is exactly same as $C_1U + C_2U$. We are essentially talking about let me mark it, this distance. So this distance is nothing but W_1U , this much is W_2U and this much is W_1U . You can alternatively think that this one is C_2U and this portion is C_1U .

That is you can say it as either in terms of W_2U and W_1U or you can say this portion is C_2U and this portion is C_1U . So I guess you now understand that what is the reason behind this derivation. So you see that $W_1^2 - W_2^2 = W_1U - W_2U$ times $W_1U + W_2U$ and $W_1U + W_2U$ is nothing but $C_1U + C_2U$. So we can say that the degree of reaction R then becomes $W_1U - W_2U$ whole divided by $2U$.

(Refer Slide Time: 25:00)

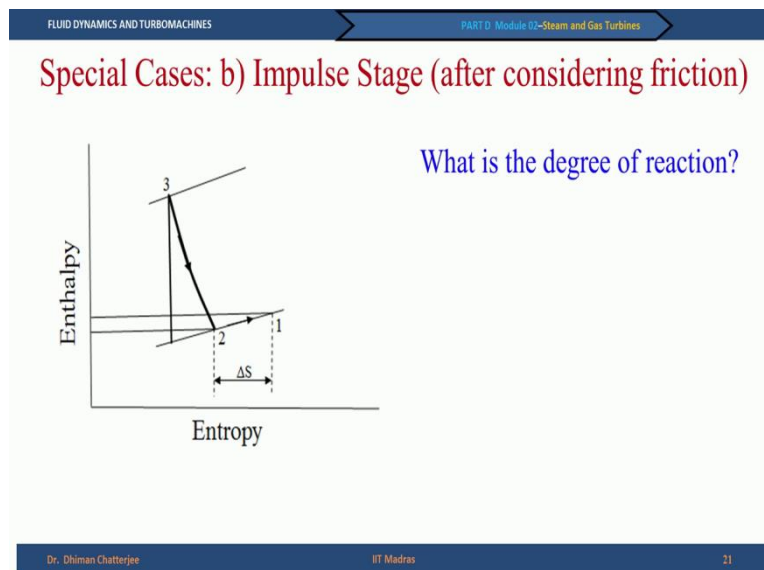

So if we continue the discussion further on the degree of reaction and we can write that W_{1U} is $CM \cot \beta_1$, so W_{1U} is $CM \cot \beta_1$ and W_{2U} is $CM \cot \pi - \beta_2$ because β_2 is this angle, hence we are talking about this angle which is $\pi - \beta_2$ or $-\beta_2$. So I can write also in terms of the blade angles and hence I write that R equal to $CM \tan \beta_1 + \cot \beta_2$, whole divided by $2U$. And now let us take some special cases.

Let us say R equal to 0, which means the numerator has to be 0. Now CM cannot be 0 because in that case there is no mass flow rate. If there is no mass flow rate, then there is no question of the turbine performance. So the only way R can be 0 is if this bracketed term is 0, which means that β_1 is $\pi - \beta_2$. So we see that in case of the impulse turbine R equal to 0, we get back the symmetric blade condition which we have already discussed earlier. So we get back and you can draw the velocity triangle which we have discussed earlier.

Now let us look at 2 cases of R equal to 0, 1 with friction and other without friction. Let us start without friction. So in case of without friction we see that the expansion takes place in the nozzle from 3 to 2. Since R equal to 0, we know that H_2 equals to H_1 and there is no pressure drop, so 2 and 1 becomes coincident points. In case of the frictional case, we know that the pressures cannot be same, however R equal to 0 forces me to say that H_2 equals to H_1 . So 3 to 2 is an expansion in the nozzle, then this is a horizontal line and this point is your point one.

So what we find that there is an entropy increase because there is a friction and the pressure has reduced. So in this case strictly speaking, even though we get R equal to 0 from the enthalpy definitions, there is a pressure change.

(Refer Slide Time: 27:31)

And if we consider that, if we want to insist that we want an impulse stage, that is we want the pressure not to change, then what happens, the 2 and 1, the points 2 and 1 should lie on the same pressure curve. So in that case what happens is 3 to 2 is an expansion in the nozzle and then it goes from 2 to 1 because there will be an increase in entropy because friction is present and we find that H_1 has become more than H_2 . Recollect what is the definition of R , let us go back and write, see the definition of R once again.

We will see that R is H_2 minus H_1 . Now in the case of friction and impulse stage, we find that in the case of friction with impulse stage, we find that H_1 is more than H_2 , which means H_2 minus H_1 is negative. So what happens to the degree of reaction, you can find out now. So it is actually going to be negative. So let us try to get these points back in our minds again. So 1st is when we say R equal to 0, in the idealised case of no friction, there is no issues. Because points 2 and 1 are coincident points, so H_2 minus H_1 is 0, the pressure is, now there is no pressure drop, P_2 equal to P_1 .

The moment we insist that R is equal to 0 and there is friction, then what happens, the pressure should drop though enthalpy should remain same. So H_2 equal to H_1 is honoured but not pressure P_2 equal to P_1 . So in that case we find that strictly speaking, definition of impulse stage, that is no pressure drop is not valid. Whereas if we want to insist that there is no pressure drop but there is friction, then we find the degree of reaction becomes negative.

(Refer Slide Time: 29:46)

FLUID DYNAMICS AND TURBOMACHINES PART D: Module 02—Steam and Gas Turbines

Special Cases: c) R=0.5

$$W_{1u} = C_m \cot \beta_1 = U + C_m \cot(\pi - \alpha_1)$$

$$W_{2u} = C_m \cot(\pi - \beta_2) = -C_m \cot \beta_2 = C_m \cot \alpha_2 - U$$

$$\begin{aligned}
 W_{1u} - W_{2u} &= C_m \cot \beta_1 + U - C_m \cot \alpha_2 \\
 &= U + C_m (\cot \beta_1 - \cot \alpha_2) \\
 &= U + C_m (\cot \beta_2 - \cot \alpha_1)
 \end{aligned}$$

$$\begin{aligned}
 R &= 0.5 + \frac{C_m (\cot \beta_2 - \cot \alpha_1)}{2U} \\
 &= 0.5 + \frac{C_m (\cot \beta_1 - \cot \alpha_2)}{2U}
 \end{aligned}$$

$\beta_1 = \alpha_2$ and $\beta_2 = \alpha_1$

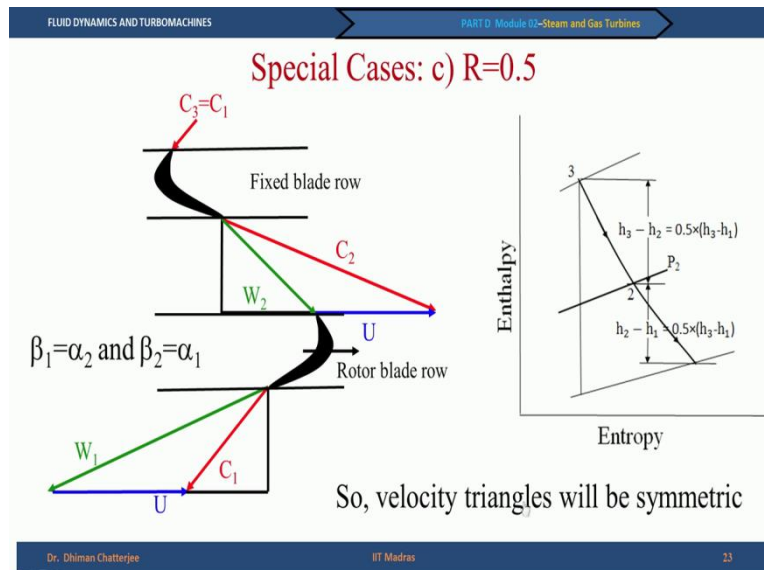

Dr. Dhiman Chatterjee
IIT Madras
22

So this has to be kept in mind and another important special case that I will consider now is R equal to 0.5. So I write in the same way that W_{1u} equal to $C_m \cot \beta_1$ is equal to U plus $C_m \cot \pi$ minus α_1 and W_{2u} is $C_m \cot \pi$ minus β_2 is equal to minus $C_m \cot \beta_2$ and I write it in terms of $C_m \cot \alpha_2$ and U . So basically I am trying to use the blade angles which is β_1 and β_2 and the nozzle directed angles of the absolute velocities α_1 and α_2 .

So then if I write W_{1u} minus W_{2u} , I can get an expression in terms of the velocities U and C_m and α and β . So we get it that $C_m \cot \beta_1$ which we get from here minus $C_m \cot \alpha_2$ plus U . Why am I getting it, because I am talking about minus W_{2u} . So minus W_{2u} will give me minus $C_m \cot \alpha_2$ and plus U . So then I tried U plus C_m common $\cot \beta_1$ minus $\cot \alpha_2$ or I did not terms of $\cot \beta_2$ to minus $\cot \alpha_1$. What does it mean, it means that I can write R equal to $0.5 + \frac{C_m (\cot \beta_2 - \cot \alpha_1)}{2U}$, because this definition of $R = \frac{W_{1u} - W_{2u}}{2U}$ is already discussed.

So then we get, in case I want to insist that R has to be 0.5, then this entire expression which is shown here, this entire expression which is shown here has to go to 0. So this term, this bracketed term as to go to 0. And it can go to 0 only if following the same logic case β_2 equal to α_1 or from the 2nd expression, β_1 equal to α_2 . So what we get in case of degree of reaction or reaction ratio of 0.5 β_1 equal to α_2 and β_2 equal to α_1 .

(Refer Slide Time: 32:11)

And we can draw the velocity triangles and the enthalpy and entropy diagram. First let us see the enthalpy entropy diagram, we see that $H_3 - H_2$, this is exactly same as $H_2 - H_1$ so that the total enthalpy drop $H_3 - H_1$ is half of, is double of this $H_3 - H_2$ or $H_2 - H_1$ giving me reaction ratio or degree of reaction and 0.5. And you see that C_3 equal to C_1 , the normal stage has been assumed and we get C_3 equal to C_1 which comes out with C_1 , which comes in at a stage is C_3 .

And $\beta_1 = \alpha_2$ and $\beta_2 = \alpha_1$ and hence velocity triangles will be symmetric. Please do not confuse this velocity triangles will be symmetric with the symmetric blading assumption that we have talked about earlier.

FLUID DYNAMICS AND TURBOMACHINES PART D: Module 02- Steam and Gas Turbines

Special Cases: d) $R=1$

$\triangleright h_3 = h_2$

$$R = \frac{W_{u1} - W_{u2}}{2U}$$

$$= 1 - \frac{C_m}{2U} (\cot \alpha_1 + \cot \alpha_2)$$

$\rightarrow \alpha_1 = \pi - \alpha_2$

Draw velocity triangles and h-s plot

Dr. Dhiman Chatterjee
IIT Madras
24

And finally the special case which we are talking about is R equal to 1. In this case what we get is H3 equal to H2 and we can say that R equal to 1 with this expression in terms of velocity triangles is $W_{u1} - W_{u2}$ by $2U$ will give me $1 - \frac{C_m}{2U} (\cot \alpha_1 + \cot \alpha_2)$ plus $\cot \alpha_2$ and hence we get $\alpha_1 = \pi - \alpha_2$. I suggest that to get a practice, you can draw the velocity triangles and the HS plot for this case as well. Please note we are talking about R equal to 1.

Typical velocity triangles for 2-row velocity compounded turbine

$m X_n$: Velocity component X for stage m and pressure/suction side (i.e. 2 or 1)

Dr. Dhiman Chatterjee
IIT Madras
25

I will, we can extend this discussion from a single stage to multiple stages, I will show you a simple example of typical velocity triangles for 2 row velocity compound a turbine and I

leave it to you to do the other parts. So first you have to recollect that a velocity compounded turbine, the first stage has a nozzle and the 2nd stage has a stator or the guide blade or the fixed blade. So the flow is directed from the nozzle to the 1st stage rotor and the flow leaves the 1st stage rotor and goes into the 2nd stage which is having a stator and then from the stator it goes to the 2nd stage rotor and leaves.

So we can say that the velocity is defined in terms of MXN , we are now using 2 subscripts, the 1st subscript of M talks about M th stage, for example if it is stage 1, all of these quantities C , W , etc. will have 1 as the M . And N refers to the pressure and suction sides which is talking about 2 and 1. So that means when it enters the rotor, it is 2 and when it leaves the rotor, it is 1. Thus we have for the 1st stage, for the rotor, velocity can be given as $1W2$ at the inlet, relative velocity and the relative velocity at the exit of the 1st stage rotor can be given as $1W1$. And similarly we can talk about $2W2$ and $2W1$ for the 2nd stage rotor respectively. And this is the stage one, this pink line shows and the stage 2.

FLUID DYNAMICS AND TURBOMACHINES

PART D Module 02 - Steam and Gas Turbines

Summary

- Degree of reaction and velocity triangles are shown for different cases

Dr. Dhiman Chatterjee IIT Madras 29

And with this I come to the conclusion of today's discussion which we had on the degree of reactions, we talked about different special cases starting from the generalised description of degree of reaction in terms of enthalpy and the velocity components. And then we connected and showed what will be the HS plot for different degrees of reaction in particular for R equal to 0 or the impulse stage or R equal to 0.5. We have talked about the requirements of the velocity triangles and from there we talked about the requirements of the blades.

We talked about the symmetric blading when we talked about that β_1 and β_2 are connected with the relationship that $180^\circ - \beta_1 = \beta_2$ and we also talked about the symmetric velocity triangles when we talked about, when we talked about R equal to 0.5. With this I stop and in the next class we will talk about the few tutorial problems we want to discuss to bring clarity to do discussion we had done so far. Thank you.
