Lecture – 11
Uncertainty Analysis

Hello, I welcome you all in this course of Mechanical Measurement Systems and today we will discuss Uncertainty Analysis. And we were we will we will mainly focus on Uncertainty Analysis and will solve certain numerical related with the uncertainty analysis.

(Refer Slide Time: 00:36)

Topics to be covered

- Uncertainty analysis
- Numerical

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

(Refer Slide Time: 00:41)

So far, we have gone through the error in measurement and error in measurement is always established as measured value minus true value. In most of the cases, we do not have true values. We are we have the values which are very close to the true value, but exactly exact estimation of true value is difficult right.

So, there is always uncertainty in error measurement right. Now, in uncertainty analysis what we do, we estimate the magnitude of error. Suppose, we are measuring voltage with the help of a voltmeter and the voltage is let us say 100 volts and there is an error in the measurement of let us say of there of 2 percent. When we say uncertainty in the measurement is 0 to 2 percent, it means error in the measurement may lie in this range right. It cannot be exactly 2 percent it may lie in this range.

So, the Uncertainty Analysis it assigns the credible limits to the accuracy of report reported value. So, we report any value. So, it provides the credible limit to the reported value. And when we want to do the uncertainty analysis, there is a little mathematics is involved.

(Refer Slide Time: 02:10)

Uncertainty Analysis

$$y = f(x_1, x_2, x_3, \dots, x_n)$$
$$y + \Delta y = f(x_1 + \Delta x_1, x_2 + \Delta x_2, x_3 + \Delta x_3, \dots, x_n + \Delta x_n)$$
$$f(x_1 + \Delta x_1, \dots, x_n \pm \Delta x_n)$$
$$= f(x_1, x_2, \dots, x_n) + \Delta x_1 \frac{\partial f}{\partial x_1} + \Delta x_2 \frac{\partial f}{\partial x_2} + \dots + \Delta x_n \frac{\partial f}{\partial x_n}$$
$$+ \frac{1}{2} \left[(\Delta x_1)^2 \frac{\partial^2 f}{\partial x_1^2} + \dots \right] + \dots$$

Prof. RAVI KUMAR
Department of Mechanical & Industrial Engineering

(Refer Slide Time: 02:20)

Handwritten notes on a whiteboard:

$$y = f(x_1, x_2, x_3, \dots, x_n)$$

Diagram illustrating error propagation for the equation $Q = m C_p \Delta T$:

- $Q = m C_p \Delta T$
- Mass flow rate m is measured in kg/s with error ϵ_1 .
- Temperature change ΔT is measured in $^\circ\text{C}$ with error ϵ_2 .
- The total error in Q is $Q = \epsilon_1 + \epsilon_2$.

Suppose, there is a function y, x_1, x_2, x_3 and x_n right, I will give you an example for example; we are measuring heat carried away by the cooling water in a condenser.

So, that is going to be Q is equal to $m C_p \Delta T$. Now, here two things will be measured; one is mass flow rate in kg per second and ΔT in degree centigrade . And while doing this measurement, it will incorporate certain error and this will also measurement of temperature where also incorporate certain error in may be

expressed in terms of percentage or absolute terms in degree centigrade ok, kg per second.

Now, these two errors will be accumulated. Suppose, this has a 1 error and this has sorry let us say this has e_1 error and this has this one Δt has e_2 error. So, error in Q shall it be e_1 plus e_2 , it will not it will not.

(Refer Slide Time: 03:52)

So, in order to find this when y is a function of here because mass flow rate is a function of is a function of sorry not mass flow rate, heat transfer heat transfer is a function of heat transfer rate is mass flow rate and ΔT .

Similarly, we have taken here some y is a function of x_1, x_2, x_3 and going up to x_n then, Y plus ΔY right. Change in y due to error in a measurement 1, 2, 3 and 4 it has to be estimated right. We cannot determine this. This has to be estimated.

(Refer Slide Time: 04:52)

$$y = f(x_1, x_2, x_3, \dots, x_n)$$
$$y + \Delta y = f(x_1 + \Delta x_1, x_2 + \Delta x_2, \dots, x_n + \Delta x_n)$$
$$y + \Delta y = f(x_1, x_2, x_3) + \Delta x_1 \frac{\partial f}{\partial x_1} + \Delta x_2 \frac{\partial f}{\partial x_2} + \frac{1}{2} \left[(\Delta x_1)^2 \frac{\partial^2 f}{\partial x_1^2} + \dots \right]$$

So, this is going to be equal to $f(x_1 + \Delta x_1, x_2 + \Delta x_2)$ and so on and it will go up to $x_n + \Delta x_n$ their cumulative effect.

Now, this function can further be modified as $f(x_1, x_2, x_3) + \Delta x_1 \frac{\partial f}{\partial x_1} + \Delta x_2 \frac{\partial f}{\partial x_2}$ right. So, this function is partially differentiated with Δx_1 multiplied by $\frac{\partial f}{\partial x_1}$, partially differentiate Δx_2 multiplied by $\frac{\partial f}{\partial x_2}$ plus half we can continue with this series $\Delta x_1^2 \frac{\partial^2 f}{\partial x_1^2}$ plus and so on. So, but these values will be neglected and they will be rounded off and now, we have $y + \Delta y$.

So, this y and this $y + \Delta y$ will be they will be cancelled and we will be getting just a minute.

(Refer Slide Time: 06:20)

$$\Delta y = \Delta x_1 \frac{\partial f}{\partial x_1} + \Delta x_2 \frac{\partial f}{\partial x_2} + \dots \Delta x_n \frac{\partial f}{\partial x_n}$$
$$U_y = \sqrt{\left(u_{x_1} \frac{\partial f}{\partial x_1}\right)^2 + \left(u_{x_2} \frac{\partial f}{\partial x_2}\right)^2 + \dots + \left(u_{x_i} \frac{\partial f}{\partial x_i}\right)^2}$$

IIT ROORKEE | NFTEL ONLINE CERTIFICATION COURSE | Prof. RAVI KUMAR | Department of Mechanical & Industrial Engineering | 4

And we will be getting delta y as delta x 1 del f by del x 1 plus delta x 2 del f by del x 2.

(Refer Slide Time: 06:27)

The image shows a handwritten derivation of the error propagation formula. At the top, the total differential is written as $\Delta y = \left(\frac{\partial f}{\partial x_1} \Delta x_1 + \frac{\partial f}{\partial x_2} \Delta x_2 + \dots + \frac{\partial f}{\partial x_n} \Delta x_n \right)$. Below this, the error in the function, U_y , is given by the square root of the sum of the squares of the individual error terms: $U_y = \sqrt{\left(u_{x_1} \frac{\partial f}{\partial x_1}\right)^2 + \left(u_{x_2} \frac{\partial f}{\partial x_2}\right)^2 + \dots + \left(u_{x_n} \frac{\partial f}{\partial x_n}\right)^2}$. A circled plus sign is written below the error term, and the absolute values of the error terms are shown as $|\Delta x_1| + |\Delta x_2| + \dots$. At the bottom, the total differential is written again with the error terms circled: $\Delta y = \left(\frac{\Delta x_1}{-}\right) \frac{\partial f}{\partial x_1} + \left(\frac{\Delta x_2}{-}\right) \frac{\partial f}{\partial x_2} + \dots + \left(\frac{\Delta x_n}{-}\right) \frac{\partial f}{\partial x_n}$.

And it will go on up till del x n delta f by del x n right. Now, the question is, now this is differentiation of with respect to the first parameter error in first parameter, with respect to second parameter; error in second parameter and the nth differentiation with partial differentiation with nth parameter this is only error in error in measurement delta x 1, delta x 2, delta x 3.

Now, this error in measurement, we are considering as uncertainty in measurement right and then, we can have the final expression as uncertainty in the measurement of y is equal to under root uncertainty in the measurement of 1 or x 1 then, Δf by Δx_1 whole square plus uncertainty in the measurement of x 2 Δf del x 2 whole square plus uncertainty in measurement of x 3 del f f by del x 3 whole square and. So on up to nth term.

Now, the question is why we are adding squaring and adding or it is known as the Pythagorean sum. Why we are not simply adding these values right. This question may arise and for this purpose first of all the purpose of this is that any plus minus contribution is not accidentally canceled. Any contribution in the uncertainty by the virtue of being x 1 delta x 1 positive or negative, they are not accidentally canceled. Suppose, this is negative error; this is positive error. This is delta x 2 is positive; this delta x 1 negative, this should not be. In fact, module of these has to be added, module of delta x 1 plus module of delta x 2 like this.

So, in order to ensure that accidentally it is not done, square has been taken. Now, second thing is in this case, large source of error is magnified, large source of error is magnified reason being for example, error in the measurement is let us say there two measurements x 1 and x 2, x 1 the measurement error is 12 percent, x 2 measurement error is 5 percent right.

(Refer Slide Time: 09:30)

The image shows a handwritten derivation of the uncertainty propagation formula. At the top, the formula is written as:

$$U_y = \sqrt{\left(U_{x_1} \frac{\partial f}{\partial x_1}\right)^2 + \left(U_{x_2} \frac{\partial f}{\partial x_2}\right)^2 + \left(U_{x_3} \frac{\partial f}{\partial x_3}\right)^2 + \dots}$$

Below the formula, a numerical example is provided:

$$x_1 = 12\%$$

$$x_2 = 5\%$$

$$x = 13\%$$

The values 12% and 5% are circled, and a checkmark is next to the 13% result, indicating the final combined uncertainty.

So, now here if we take the Pythagorean sum, you will know that the final error will be 13 percent not the 17 percent that is another reason for taking because this is the worst case scenario. This will rarely happen right. So, this when we take the Pythagorean sum, all these issues are addressed. So, so we never operate in this case, we never operate in extreme worst case scenario. This is the extreme worst case scenario right.

So, for this reason the Pythagorean sum of all the errors all the uncertainty in the measurement is taken. And suppose is now we will take certain cases for example, there is the case of addition.

(Refer Slide Time: 10:11)

The image shows handwritten mathematical derivations on a whiteboard. At the top, the function $R = a_1 x_1 + a_2 x_2 + \dots + a_n x_n = \sum_{i=1}^n a_i x_i$ is written. Below it, the partial derivative $\frac{\partial R}{\partial x_i} = a_i$ is shown. The uncertainty in R is given by $U_R = \left[\sum_{i=1}^n (a_i u_{x_i})^2 \right]^{1/2}$. To the right, a diagram shows a horizontal line with two downward arrows labeled T_1 and T_2 , representing a temperature difference. Below the diagram, the equation $Q = m C_p (T_2 - T_1)$ is written, followed by $F(\Delta T)$. At the bottom left, the temperature difference $\Delta T = T_1 - T_2$ is defined, and its uncertainty is calculated as $U_{\Delta T} = \left[(0.1)^2 + (0.1)^2 \right]^{1/2}$.

Now, R maybe the some function R is $a_1 x_1$ plus $a_2 x_2$ plus $a_n x_n$ right or it is sum of $a_i x_i$, i is equal to 1 to n fine.

Now, $\frac{\partial R}{\partial x_i}$ by $\frac{\partial R}{\partial x_i}$. So, or is equal to a_i for any, if I differentiate with the x_1 a_1 , x_2 a_2 , x_n . And so, uncertainty in the measurement of R is going to be the sum of $a_i u_{x_i}$ whole square raise to power 1 by 2, I is equal to 1 to sorry here. I is equal to 1 to I is equal to n fine. For example, I will give you one example suppose we are measuring the temperature with the help of thermocouples and again the temperature or the heat carried away by the cooling water in a condenser right. Inlet temperature is T_1 , outlet temperature is T_2 fine.

Now, Q is definitely heat transfer rate is mass flow rate Cp T 2 minus T 1. Now, error in the measurement of Q or error in the measurement of delta T in the measurement of delta T, so, delta T is T 1 minus T 2. So, uncertainty in the measurement of delta T is going to be as per this. Suppose, error in measurement this is 0.1 and this is also 0.1. So, 0.1 degree centigrade error in the measurement of T1 and T 2 also it is 1 degree centigrade, a 1 ai is 1 in this case, ai is 1. So, we can take 0.1 whole square plus 0.1 whole square raise to power 1.2.

(Refer Slide Time: 13:44)

Handwritten mathematical derivation showing the calculation of uncertainty in temperature difference:

$$U_{\Delta T} = \sqrt{0.01 + 0.01} = 0.141^\circ\text{C}$$

$$T_1 = \frac{T_a + T_b}{2}$$

$$U_{T_1} = \left[\left[\frac{1}{2} (0.1) \right]^2 + \left[\frac{1}{2} (0.1) \right]^2 \right]^{1/2} = \left[\frac{0.01}{4} + \frac{0.01}{4} \right]^{1/2} = \frac{1}{2} \left[0.02 \right]^{1/2} = 0.0707$$

Diagram showing temperature difference $\Delta T = T_2 - T_1$ with arrows indicating the direction of temperature change.

$$Q = m C_p (T_2 - T_1)$$

$$E(\Delta T)$$

So, when we take 0.1 square, then it becomes the uncertainty in delta T uncertainty in delta T is equal to under root of 0.0 1 plus 0.01. Now, if we take under root of 0.02, it becomes 0.141 degree centigrade right. So, temperature difference individual measurement is 0.1 and 0.1 right. So, it is not 0.2, it is 0.14141 degree centigrade in uncertainty measurement of delta T.

On the other side, inlet temperature is measured by 2 thermocouples. For example, inlet temperature is measured by 2 thermocouples. So, each thermocouple has accuracy of 0.1 degree centigrade. So, T 1 is Ta plus Tb which are a fixed at the inlet divided by 2. So, uncertainty in the measurement of T 1 is going to be equal to half, a a 1 is half and uncertainty is 0.1 square plus again half 0.1 square right and then we get.

Student: Whole square.

Now, we get 0.01 divide by 4 plus 0.01 divide by 4 raise to power 1 by 2 or we can say it is half of 0.02 raised to power 1 by 2 or it is 0.0705. So, you can see; when we are putting tube thermocouples, we have improved the uncertainty in the measurement. Likewise, you can have bunch of thermocouples. If we take the average value the uncertainty the measurement or accuracy of the measurement shall improve.

Now, after this we will take up a case where we have R as product of different parameters R is a product of different parameters.

(Refer Slide Time: 16:36)

Uncertainties for Product Functions

$$R = x_1^{a_1} \cdot x_2^{a_2} \cdot x_3^{a_3} \dots \dots x_n^{a_n}$$

$$\frac{\partial R}{\partial x_i} = x_1^{a_1} \cdot x_2^{a_2} \cdot x_3^{a_3} \left(a_i x_i^{a_i-1} \right) \dots \dots x_n^{a_n}$$

$$\frac{1}{R} \frac{\partial R}{\partial x_i} = \frac{a_i}{x_i}$$

$$\frac{U_R}{R} = \left[\sum \left(\frac{a_i U_{x_i}}{x_i} \right)^2 \right]^{\frac{1}{2}}$$

IIT ROORKEE
 NPTL ONLINE
CERTIFICATION COURSE

Prof. RAVI KUMAR
 Department of Mechanical & Industrial Engineering

5

So, that is x 1 raise to power a 1, x 2 raised to power a 2, x 3 raised to power a 3, x n a to power n.

(Refer Slide Time: 16:52)

$$R = x_1^{a_1} x_2^{a_2} x_3^{a_3} \dots x_i^{a_i} \dots x_n^{a_n}$$

$$\frac{\partial R}{\partial x_i} = x_1^{a_1} x_2^{a_2} \dots (a_i x_i^{a_i-1}) \dots x_n^{a_n}$$

$$= \frac{a_i R}{x_i}$$

$$\left(\frac{\partial R}{R}\right) = \frac{a_i \partial x_i}{x_i}$$

$$= \left[\sum_{j=1}^n \frac{a_j U_{x_j}}{x_j} \right]^{1/2} R$$

$Nu = 0.023 Re^m Pr^n$

So, these are the cases. For example, Reynolds number those who are mechanical they very well know some constant for example, flow in a pipe 0.023 Reynolds number m Prandtl number n this is 0.8 and this is 1 by 3.

So, such type of relations we have in mechanical engineering. So, R is again del R over del xi because xi here xi is equal to x 1 a a 1 multiplied by x 2 a 2 and when we differentiate xi or this is this we can take xi x n when we take xi and a to power i right, it becomes ai xi a minus 1 and then, we go up to x n right or we can write this as R by xi and this is ai this can be always be written as ai because this if we numerator denominator if you multiply by xi, then again you will be getting this expression. Likewise, you can do for n number of values and ultimately you will find that this R can come down here.

So, del R by R is equal to ai del xi by xi right. And when we say the uncertainty in the measurement, it can be expressed in terms of percentage because it is del R by R. It can be expressed as sigma ai u xi this is uncertainty in xi divided by xi I is equal to 1 to n raised to power 1 by 2 right. So, this is how the uncertainty this will be in terms of percentage. If you want to have extra value, so and absolute value, then it has to be multiplied by R right. So, both the cases we have discussed.

Now, will go for certain numerical; because solved examples will give you the inside of the things.

(Refer Slide Time: 19:40)

Example-1

The resistance of a certain size of copper wire is given as

$$R = R_0(1 + \alpha(T - 25))$$

where $R_0 = 15\Omega \pm 0.4$ percent is the resistance at 25°C , $\alpha = 0.005 \text{ } ^\circ\text{C}^{-1} \pm 1$ percent is the temperature coefficient of resistance, and the temperature of the wire is $T = 100 \pm 1 \text{ } ^\circ\text{C}$. Calculate the resistance of the wire and its uncertainty.

Prof. RAVI KUMAR
Department of Mechanical & Industrial Engineering

Let us start with the solved example number 1. Now, in solved example number 1. It states the resistance of a certain size of copper wire is given as R is equal to R o 1 plus alpha T minus 25.

(Refer Slide Time: 20:09)

Handwritten calculations for Example 1:

$$R = R_0 [1 + \alpha(T - 25)]$$
$$R_0 = 15\Omega \pm 0.4\% \text{ at } 25^\circ\text{C}$$
$$\alpha = 0.005 \pm 1\%$$
$$T = 100 \pm 1^\circ\text{C}$$
$$R = 15 [1 + 0.005(100 - 25)]$$
$$= 20.625\Omega$$
$$\frac{\partial R}{\partial R_0} = 1.375$$
$$\frac{\partial R}{\partial R_0} = [1 + \alpha(T - 25)]$$
$$= 1 + 0.005 \times 75$$
$$= 1.375$$
$$\frac{\partial R}{\partial \alpha} = R_0(T - 25)$$
$$= 15 \times 75 = 1125$$
$$\frac{\partial R}{\partial T} = R_0 \alpha = 15 \times 0.005$$
$$= 0.075$$

R is equal to R o 1 plus alpha t minus 25. This is the variation of resistance with temperature ok. Where R o is 15 ohm plus R o is 15 ohms plus 0.4 degree centigrade plus minus 4 degree centigrade at 25 degree centigrade right. Alpha is equal to 0.005 plus minus 1 percent. It is in terms of percentage right. Temperature coefficient of resistance

in the temperature of wire is T again 100 ± 1 degree centigrade right. Calculate the resistance of the wire and its uncertainty, so, the resistance of the wire at 100 degree centigrade.

So, it is very simple. R is equal to R_0 , R_0 is $15 \pm 0.005 T$ minus T is 25 , sorry T is 100 ± 1 minus 25 and this will give the final resistance and it is going to be 0.005 into 20.625 . So, it is 20.625 ohms. Now, we have to find the uncertainty in the measurement.

So, we will differentiate R with respect to R_0 , R with respect to α , R with respect to T right. So, $\frac{\partial R}{\partial R_0}$ is equal to $1 + \alpha(T - 25)$ right. So, it is equal to $1 + 0.005$ into $T - 25$ is 75 and this that will turn out to be 1.375 . Let us confirm this 75 into 0.005 plus 1 1.375 . Now, $\frac{\partial R}{\partial \alpha}$. When we are differentiating this with respect to α will be getting only $R_0(T - 25)$. So, R_0 is how much 20.625 into 75 . So, you will be getting 15 into this is $T - 25$ is 75 . So, 15 into 75 , it is going to be equal to 1125 15 into 75 , 1125 .

Now, $\frac{\partial R}{\partial T}$ with respect to temperature. Now, when we are doing due to the respective temperature, it is only $R_0 \alpha$ right and that is going to be equal to 15 into 0.005 and that is equal to 0.075 sorry not 0.075 ok. So, now, we have partial differentiation of R with respect to R_0 , α and T .

(Refer Slide Time: 24:56)

$$\frac{\partial R}{\partial R_0} = 1 + \alpha(T - 25)$$

$$\frac{\partial R}{\partial \alpha} = R_0(T - 25)$$

$$\frac{\partial R}{\partial T} = R_0 \alpha$$

$$R_0 = 15 \Omega \pm 0.4\% \text{ at } 25^\circ\text{C}$$

$$\alpha = 0.005 \pm 1\%$$

$$T = 100 \pm 1^\circ\text{C}$$

$$R = 15 \left[1 + 0.005(100 - 25) \right]$$

$$= 20.625 \Omega$$

$$\frac{\partial R}{\partial R_0} = 1.375$$

$$U_R = \left[(1.375 \times 0.006)^2 + (1125 \times 5 \times 10^{-5})^2 + (0.075 \times 1)^2 \right]^{1/2}$$

$$= \left[6.806 \times 10^{-3} + 3.164 \times 10^{-3} + 5.625 \times 10^{-3} \right]^{1/2}$$

$$= (15.595 \times 10^{-3})^{1/2} = 0.125 \Omega$$

Now, using this information let us note $\frac{\Delta R}{R_0}$ is equal to 1.375. $\frac{\Delta R}{\Delta \alpha}$ is equal to 1125 and unit we can write ohm and α is the degree centigrade and this is going to be unit less $\frac{\Delta R}{\Delta T}$ is equal to 0.075 ohm per degree centigrade. Now, uncertainty in the determination of R not measurement of R; in the determination of R is uncertainty in the determination of R is partial differentiation R with R_0 right and error in the measurement of R_0 .

So, partial differentiation is 1.375, error in the measurement of R_0 is 0.4 percent of 15. 0.4, this is percent not degree centigrade 0.4 percent. So, it is going to be 0.06. 0.4 percent will square this plus again next α it is 1125 multiplied by uncertainty in this. So, 5×10^{-3} , 5×10^{-5} so, it is going to be 5×10^{-5} whole square plus temperature.

So, uncertainty in temperature 0.075 so, this partial derivative of temperature is 0.075 and uncertainty in the measurement is 1 degree centigrade right. So, it is 1 and square is taking and will take under root of entire expression. So, this is going to be like this. Now, this value is 6.806×10^{-3} plus 3.164×10^{-3} plus 5.625×10^{-3} raise to power 1 by 2 right.

And here, if you see that highest contribution in uncertainty is coming from here and this is $\frac{\Delta R}{\Delta R_0}$ right. And we further resolve this and it is going to be 15.595×10^{-3} raise to power 1 by 2 and it is 0.125 ohms. This is the estimated uncertainty. We are not doing any measurement of R. So, uncertainty in the measure determination of R is 0.125 ohm. If you want to express in terms of percentage, you simply divide this.

(Refer Slide Time: 28:46)

$\frac{\partial R}{\partial \alpha} = 1125 \Omega/\%$
 $\frac{\partial R}{\partial T} = 0.075 \Omega/^\circ C$
 $R_0 = 15 \Omega \pm 0.4\% \text{ at } 25^\circ C$
 $\alpha = 0.005 \pm 1\%$
 $T = 100 \pm 1^\circ C$
 $R = 15 [1 + 0.005 (100 - 25)]$
 $= 20.625 \Omega$
 $\frac{\partial R}{\partial R_0} = 1.375$

$\frac{0.125}{20.625} \times 100 = 0.61\%$

$\left[(6.806 \times 10^{-3})^2 + (3.164 \times 10^{-3})^2 + (5.625 \times 10^{-3})^2 \right]^{1/2}$
 $= (15.595 \times 10^{-3})^{1/2} = 0.125 \Omega$

Simply divide this 1250.125 divided by this 20.625 multiplied by 100. This will give you uncertainty in the measurement in terms of uncertainty in the determination of a measure of in terms of percentage.

So, this is one example regarding determination of uncertainty in the measurement.

(Refer Slide Time: 29:15)

Example-2

The two resistors R_1 and R_2 are connected in series. The voltage drops across each resistor are measured as

$$E_{R_1} = 100V \pm 1V$$

$$E_{R_2} = 15V \pm 0.05V$$

The value of R_2 is $0.075\Omega \pm 0.25\%$. Determine power dissipated in R_1 and uncertainty.

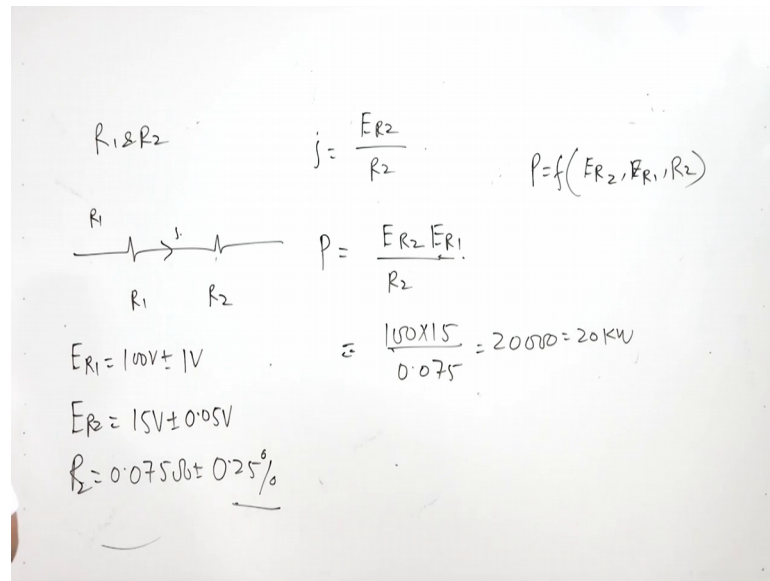

Prof. RAVI KUMAR

Department of Mechanical & Industrial Engineering

8

Another example is, if 2 resistors R 1 and R 2, they are connected in series. So, I will rub this one. There 2 resistors R 1 and R 2, they are connected in series. This is R 1 and this is R 2 right.

(Refer Slide Time: 29:39)

And voltage drop across the each registered is measured as R 1 voltage drop across the R 1 is so, E R 1 is 100 volts and plus minus 1 volt and voltage across R 2 is 15 volts plus minus 0.05 volts right.

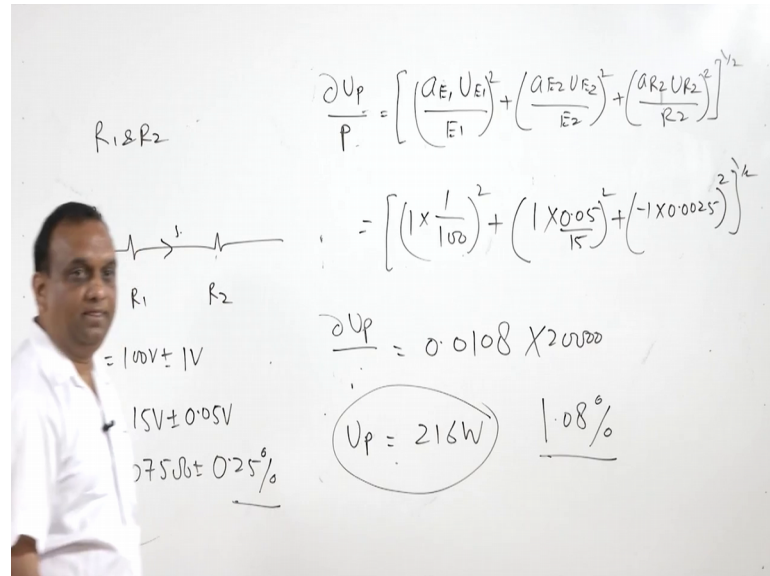

So, voltage we have measured which one voltmeter here, one voltmeter here, this voltmeter is showing 100 volts this is showing 15 volts with some error in the measurement. Now, the R 2 value is given R 2 value is 0.075 ohms plus minus 0.25 percentage. This is the percentage of measured value it is always if it is written like this, it is always measured.

So, dissipate find out determine the power dissipated in R 1, how much power is dissipated is R 1 and uncertainty in the determination of the power. Mathematically it is very simple because once R 2 is given a voltage is given. We can always measure the current and current is going to be same in both the cases. So, current is R 2 divided by R 2. And once we know the current and then we can always measure power in dissipated in the resistor one that is I R. So, I is E R 2 by R 2. This is this is current multiplied by the voltage will give the power P is equal to Va.

So, that is E R 1. Now, we have power as a function of R 2. This is this is a voltage in R 2 voltage in sorry voltage in R 1 and resistance R 2. So, power is calculated 100 into 15, but product of the voltage divided by 0.075 and it is going to be 20,000 or 20 kilowatt.

Let me check, now, uncertainty in the measurement of power, so, uncertainty in the measurement of power because now, this is a case of products right.

(Refer Slide Time: 33:10)

So, uncertainty shall be calculated as uncertainty in power divided by power is equal to a E 1 uncertainty in measurement of E 1 divided by E 1 whole square plus a E 2 uncertainty in E 2 divided by E 2 whole square plus a R 1 sorry R 2, a R 2 uncertainty in R 2 divided by R 2 whole square raise to power 1 by 2.

Now, here this values R 1 because we have because this is this a E 1 is 1, a 2 is 1 and this is minus 1 right. So, here we will calculate uncertainty in power divided by power is equal to 1 into error is 1, 1 by 100 whole square plus again a E 2 is also 1. So, 1 into 0.05 by 15 plus here it is minus 1 right. And then, it is 0.0 into 0.0025 it is given in the terms of percentage; so because it is given in the terms of percentage right.

So, this is the mathematical expression for delta U. So, here, we get if we solve this will get del U P by P as 0.0108 or error in the measurement of uncertainty in the measurement of power is 216 watt. When we multiply this by 20,000 right, then we get 0.0108 multiplied by 20 216 watt. So, this is the uncertainty in the measurement of power, it is 2 one 6 watt or if you want to express in terms of percentage, it is 1.08 of the measured value right. This is all for today.

Thank you.
