Lecture - 40
Problem solving- 2

Hello I welcome you all in this course on mechanical measurement systems, today we will solve a few new miracles related with the mechanical measurement system. Now starting with the numerical based on the first order system, the statement of the numerical is a signal described by the relation theta is equal to $3 \sin 2 t$.

(Refer Slide Time: 00:43)

Handwritten derivation on a whiteboard:

$$\theta_i = 3 \sin 2t + 0.4 \cos 10t$$

$$\lambda = 0.1 \Rightarrow \theta_i = 3 \sin 2t - 0.4 \sin(\pi + 10t)$$

$$\theta_{1A} = \frac{1}{\sqrt{\omega^2 \lambda^2 + 1}}$$

$$= \frac{1}{\sqrt{2^2 \cdot 0.1^2 + 1}} = 0.9805$$

$$\theta_A = 0.9805 \times 3 = 2.94$$

$$\phi = 11.31^\circ$$

$$\phi = \tan^{-1}(\omega \lambda)$$

$$= \tan^{-1}(2 \times 0.1) = 11.31^\circ$$

This is theta I is equal to $3 \sin 2 t$ plus $0.4 \cos 10 t$ this is a input signal. It requires to be measured by using a first order system, having a time constant of 0.1 second. So, lambda is 0.1 develop expression for the corresponding output. So, first order system is being used for the measurement and we have to write equation for the response of the instrument. First of all here when we do this first of all first order analysis of this type of input cyclic input we add only sine equations. So, cos has to be converted into the $3 \sin 2 t$ plus 0.4 or we can write minus $0.4 \sin \pi + 10 t$ right lambda is equal to 0.1.

Now, let us take theta 1 A. Now for this component the amplitude ratio is 1 by under root omega square lambda square plus 1 right and here in this case the omega is 2 omega is 2 in this case omega is 2 lambda is 0.1 right. So, amplitude ratio is going to be under root 2

square 0.1 square plus 1 and that is going to be equal to 0.9805. It means the response of the system for this input was for particularly for this input the amplitude is going to be 0.9805 into amplitude here is 3 it is going to be 2.94 ok.

And regarding the phase lag phi, phi is tan inverse omega lambda this is phase lag or phase angle is tan inverse minus omega lambda either way we can write. So, phase lag is tan inverse 2 into 0.1 it is going to be 11.31 degree. So, here. So, a 1 amplitude of A and this is phase angle is 11.31 degree.

Similarly, we can do for this, this is part A now for part B amplitude ratio for part B it is going to be again 1 by 1 plus omega lambda whole square under root omega lambda whole square under root.

(Refer Slide Time: 04:15)

$$\theta_i = 3 \sin 2t + 0.4 \cos 10t$$

$$\lambda = 0.1 \Rightarrow \begin{aligned} &= 3 \sin 2t - 0.4 \sin(\pi + 10t) \\ &= 3 \sin 2t - 0.4 \sin(\pi + 10t) \end{aligned} \quad -0.707 \times 0.4 = -0.283$$

$$R_A = \frac{1}{\sqrt{\omega^2 + 1}} = \frac{1}{\sqrt{2^2 + 1}} = 0.9805 \quad R_B = \frac{1}{\sqrt{1 + (\omega \lambda)^2}} = \frac{1}{\sqrt{1 + (10 \times 0.1)^2}} = 0.707$$

$$A = 0.9805 \times 3 = 2.94 \quad \phi = \tan^{-1}(10 \times 0.1) = 45^\circ$$

$$\phi = 11.31^\circ$$

Now here omega is that and lambda is 0.1. So, it is going to be under root 1 plus 10 into 0.1 whole square and that comes to be 0.707.

So, here amplitude is attenuated by its 0.707 and here it is 0.98 right because frequency is high. So, when the frequency is high that amplitude ratio will be low phi phase angle is equal to tan inverse omega lambda what is omega 10 into 0.1 is equal to 45 degree and this because it is amplitude is an end attenuated by a 707. So, 0.707 multiplied by 0.4 will give the amplitude and that is going to be equal to this is minus 4. So, this is minus.

So, minus 0.283. Now we have amplitudes and phase angle for or phase lag of responses in both the cases.

Now, here we can conclude that here the amplitude ratio amplitude ratio of A let us say R A is this much amplitude of ratio A is this much and this will give the amplitude of A dash or a this is phase lag of A, this is part A, for part B this is amplitude ratio R B right and amplitude in the part B is this and phase angle in part B is this.

Now, we have 4 values for amplitude this is for amplitude phase and this one is for amplitude and this is for phase angle right and we can find we can write the finalized equation as theta o that is output. Now this is input signal now the output signal is going to be $2.94 \sin 2t$ minus 11.31 this is the phase let minus $0.283 \sin 10t$ plus pi minus 45 degree right.

(Refer Slide Time: 07:01)

$$\theta_i = 3 \sin 2t + 0.4 \cos 10t$$

$$\lambda = 0.1 \Rightarrow \theta_o = \underbrace{3 \sin 2t}_A - \underbrace{0.4 \sin(\pi + 10t)}$$

$$\theta_o = \underline{2.94} \sin(2t - 11.31) - \underline{0.283} \sin(10t + \pi - 45^\circ)$$

And now this is the final response; now here we can see when the omega is high the amplitude ratio of output and input is low when the omega is low when omega is only 2 the ratio has gone up to 0.98. Now this is an observation in this case. So, lambda is equal to 0.1 in this case will give large measurement errors right larger measurement error.

So, now we will take another example, this is for the second order system. During the act of force measurement by a pressure transducers of diaphragm type.

(Refer Slide Time: 08:31)

Example-2

During the act of force measurement by a pressure transducer of diaphragm type, the system is stated to have natural frequency of 1000 Hz and a damping ratio of 60%. Determine the frequency range over which the amplitude ratio corresponding to sinusoidal input deviates by maximum amount of 10%. Consider pressure transducer to behave as a second order system.

Prof. RAVI KUMAR
Department of Mechanical & Industrial Engineering

So, during the act of force measurement by a pressure transducer of diaphragm type the system is stated to have a natural frequency of 1000 hertz. So, natural frequency of the system is 1000 hertz and damping ratio 60 percent. So, damping ratio 60 percent means zeta is equal to 0.6.

(Refer Slide Time: 08:52)

$\omega_n = 1000 \text{ Hz}$
 $\zeta = 0.6$
 $M = 1.1$
 10%
 $0.9 = \frac{1}{\sqrt{(1-\gamma^2)^2 + (2\zeta\gamma)^2}}$
 $\gamma = \sqrt{0.84}$
 ≈ 0.916
 $\frac{\omega}{\omega_n} \neq -ve$
 $\gamma^4 - 0.56\gamma^2 - 0.234 = 0$
 $\gamma^2 = \frac{0.56 \pm \sqrt{0.56^2 + 4 \times 0.234}}{2} = 0.84$

Determine the frequency range over, which the amplitude ratio corresponding to sinusoidal input deviates by maximum amount of 10 percent. So, division is 10 percent in amplitude, for sin response for the sinus order input.

So, consider transducers to behave with to consider pressure transducer to behave as second order system right. So, amplitude ratio in a second order system the amplitude of a second order system can be expressed as $\frac{1}{\sqrt{1 - r^2 + 2\zeta r}}$ by this is the amplitude ratio, this m is amplitude ratio is $1 - r^2 + 2\zeta r$ whole square, where r is equal to ω by ωn .

Now, if we consider amplitude ratio as 1 by 1.1 right here because it is a if we have to go for the this amplitude ratio 1.1. So, when it is 1.1 then we can put here M is equal to 1.1 and try to find the value of r because ζ is already known it is 0.6 right. If you simplify this equation this equation becomes $r^4 - 0.56r^2 + 0.174 = 0$.

Now, here if we take the solution of this equation, it has or both imaginary roots right both imaginary roots. So, it implies that that this is not a possible solution means we cannot go for M is equal to 1.1. Here also it is stated that the damping ratio is 0.6. So, for damping ratio 0.6 output will never be 1.1, because we are getting roots here all there are imaginary roots right. So, the if there is a there is a response of the system. So, rest of m is not exceeding 1 it means. So, we should go for the 0.9 because deviation can be on both sides plus 10 percent to minus 10 percent.

So, here m we can put 0.9, once we are putting m is equal to 0.9 then we are getting another equation then this equation is about $r^4 - 0.56r^2 - 0.234 = 0$.

Now, let us take solution of this equation, this is r^2 is equal to $0.56 \pm \sqrt{0.56^2 + 4 \times 0.234}$ divided by 2, and this will give the r value r^2 value as 0.84. So, we have replaced 1.1 by 0.9 and the equation is modified like this r^2 we are getting 0.84. So, r is equal to $\sqrt{0.84}$ and it is going to be 0.916. We will not take negative because w by $w \omega n \omega$ can never be negative right.

So, this is r is 0.916.

(Refer Slide Time: 12:58)

$$\begin{aligned}\omega_n &= 1000 \text{ Hz} \\ \zeta &= 0.6 \\ \frac{10\%}{M} &= 1.1 \\ \gamma &= \sqrt{0.84} \\ &= 0.916 \\ \omega &= 1000 \times 0.916 \\ &= 916\end{aligned}$$

So, 0.916 means if you multiply this by 1000, we will get the omega s 1000 multiplied by 0.916 it is going to be 916 this is not hertz cycles per second. So, it is 916, 916, 916 it is 916 cycle per second. So, this omega n is 1000 hertz. So, [FL]. So, omega is 1000 hertz. So, this 9.916 is multiplied by hertz and we are getting 916.

So, this is the answer for this numerical. Now another numerical will take up about the estimation of error, this is the power measurement is to be conducted by measuring voltage and current across the resistor r.

(Refer Slide Time: 14:03)

Example-3

The power measurement is to be conducted by measuring voltage and current across the resistor, R. The voltmeter has internal resistance 1000 Ω. The value of R is approximately 100 Ω. Calculate nominal value of power dissipated in R and the uncertainty for the following conditions:

$$R_m = 1000 \pm 5\%; \quad I = 5A \pm 1\%; \quad E = 500V \pm 1\%$$

 IIT ROORKEE

 NPTEL ONLINE
CERTIFICATION COURSE

Department of Mechanical & Industrial Engineering

4

So, there is a resistor R, voltage and current has to be measured across the resistor R. So, there is a resistor R parallel to R there is a voltmeter and voltmeter will have certain resistance right.

the voltmeter has internal resistance 1000. So, this R m is 1000 ohms ok. Calculate the nominal value of the power dissipated in R and uncertainty for the following condition. So, how much power is dissipated in R?

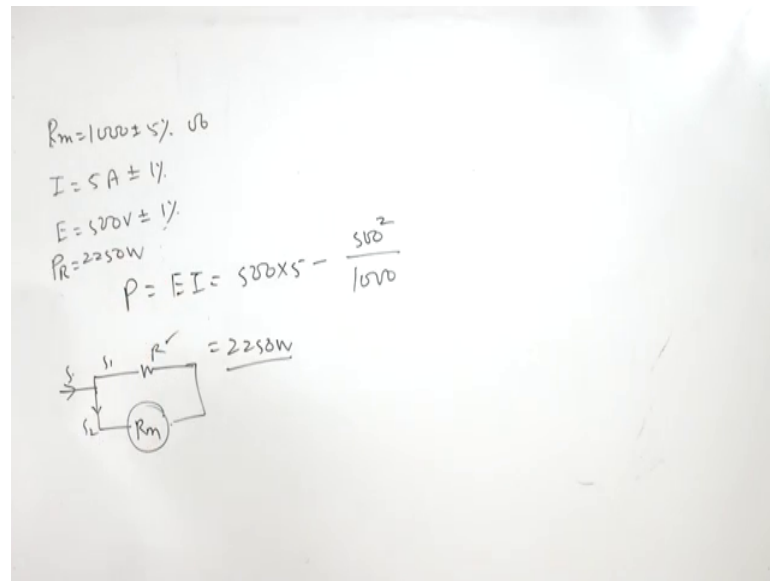

(Refer Slide Time: 15:08)

So, i is equal to let us say that, the current is splitted in 2 parts i is equal to i_1 plus i_2 this is total current it is i_1 and this is i_2 and potential difference between these 2 is E . So, i is equal to E by R plus E by R_m because they are connected in parallel. So, E will remain common or we can say that current here i_1 or E by R i_1 is equal to i minus E by R_m right because R we do not know r we do not know, but we have measured the i_1 right.

So, E is the value of E is with us, value of i is with us and value of R_m is with us. So, we have made 2 measurements, value of R is approximately it is approximately 100 ohm it is approximately not correct one right calculate the nominal value of power dissipated in the R what is that nominal power dissipated in the R . So, for dissipation of the power and R_m is when R_m is 1000 plus minus 5 percent I will right here R_m is 1000 plus minus 5 percent ohms current is 5 ampere plus minus 1 percent and E is 500 volts plus minus 1 percent ok.

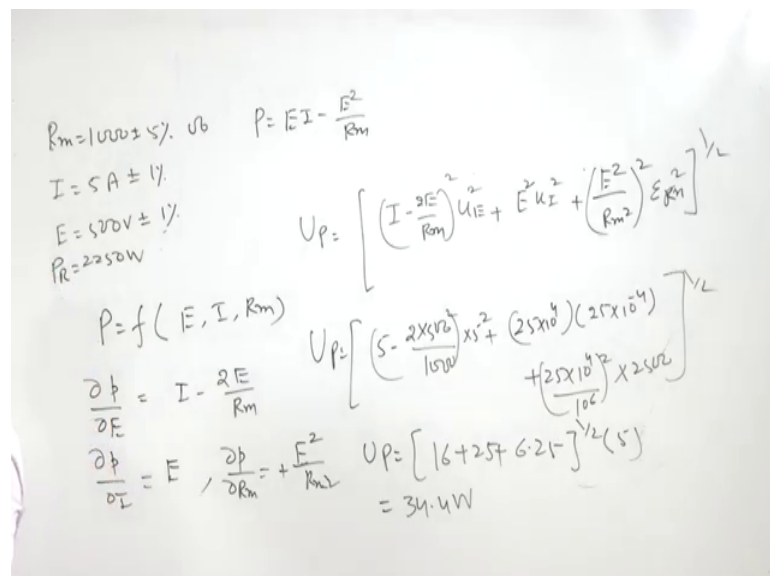

(Refer Slide Time: 17:23)

So, P is equal to simply E I. So, E is 500 into 5, 500 into 5, but this I is shared between because this I is splitted it is going to R m and 1 I is going to the resistance all I is not entering here it is I 1 and I 2. So, power dissipated will be by I 1 only. So, P is going to be this minus 500 square by 1000 E square upon r this power dissipated by this will be subtracted.

So, final power is going to be 2250 watts that is a power dissipated by R. So, P R is 2250 watts. Now we have to find uncertainty in uncertainty in the measurement.

(Refer Slide Time: 18:37)

So, power is a function of here the power is a function of E , I and R_m because we calculated P is equal to $E I$ minus E^2 upon R_m . So, it is a function of E , I and R_m right. Now we will take $\frac{\partial p}{\partial E}$ now the equation remains same $E I p$ is equal to $E I$ minus E^2 upon R_m right now $\frac{\partial p}{\partial E}$ is going to be equal to I minus $2 E$ by R_m . Now $\frac{\partial p}{\partial I}$ is going to be E and $\frac{\partial p}{\partial R_m}$ this is going to be this is 0 minus E^2 by R_m^2 and this will become plus.

Now, uncertainty in the measurement of power U_p . Uncertainty in the measurement of power is going to be I minus $2 E$ by R_m whole square, uncertainty in the measurement of E^2 plus E^2 q I^2 square right and we will use plus this is E^2 is $\frac{\partial p}{\partial a}$ uncertainty in the measurement of I , then $\frac{\partial p}{\partial R_m^2}$ square. So, E^2 by R_m^2 whole square E^2 r square whole square and then error in R_m whole square raise to power 1 watt.

Now, we can put because respective values are known to us. So, here we can put the values uncertainty in the measurement of power is 5 minus $2 E$, 2 times E is 500 divided by R_m 1000 into 5 square because we 1 percent. So, 5 100 volts and 1 percent of 5 volts is 5 ok. It is E^2 is 25 into 10 to power 4 into 25 into 10 to power minus 4 plus 25 into 10 to power 4 divided by 10 to power 6 whole square into 2500 raise to power 1 by 2 .

If we simplify this then we will be getting U_p is equal to 16 plus 25 plus 6.25 raise to power 1 by 2 multiplied by 5 and final uncertainty is 34.4 watts.

(Refer Slide Time: 22:01)

$R_m = 1000 \pm 5\% \text{ } \Omega$
 $I = 5 \text{ A} \pm 1\%$
 $E = 500 \text{ V} \pm 1\%$
 $R = 2250 \text{ } \Omega$

$$P = EI = \frac{E^2}{R_m}$$

$$U_P = \left[\left(I \cdot \frac{2E}{R_m} \right)^2 U_E^2 + E^2 U_I^2 + \left(\frac{E^2}{R_m^2} \right)^2 U_{R_m}^2 \right]^{1/2}$$

$$U_P = \left[\left(5 \cdot \frac{2 \times 500}{1000} \right)^2 (5)^2 + (500)^2 (1)^2 + \left(\frac{500^2}{1000^2} \right)^2 (2250)^2 \right]^{1/2}$$

$$U_P = \left[16 + 257 + 6.21 \right]^{1/2} (5)$$

$$= 34.4 \text{ W}$$

$\frac{34.4}{2250} \times 100 = 1.53\%$
 $R = 1000$
 500 V
 $1000 \text{ } \Omega$

If you take percentage wise now percentage wise uncertainty is 34.4 divided by 2250 into 100 and that is going to be 1.53 percent.

And uncertainty in the measurement is lowest in or bearing of the error in the measurement resistance of the voltmeter is minimum. So, if we are now here we are measuring 100, R is equal approximately R is equal to 100 100 ohms approximately and voltmeter resistance is 1000 volts 1000 ohms.

If we were measuring R of 500 ohms and voltmeter resistance is 1000 ohms then this error would have increased because substantial part of the current would have been going to the voltmeter. Contrary to this you are measuring 5 volts 5 ohms and the voltmeter resistance was 1000 volts, this would have further reduced ok. So, this is about this example of error analysis.

Now, one more example will take about the design of venturimeter.

(Refer Slide Time: 23:19)

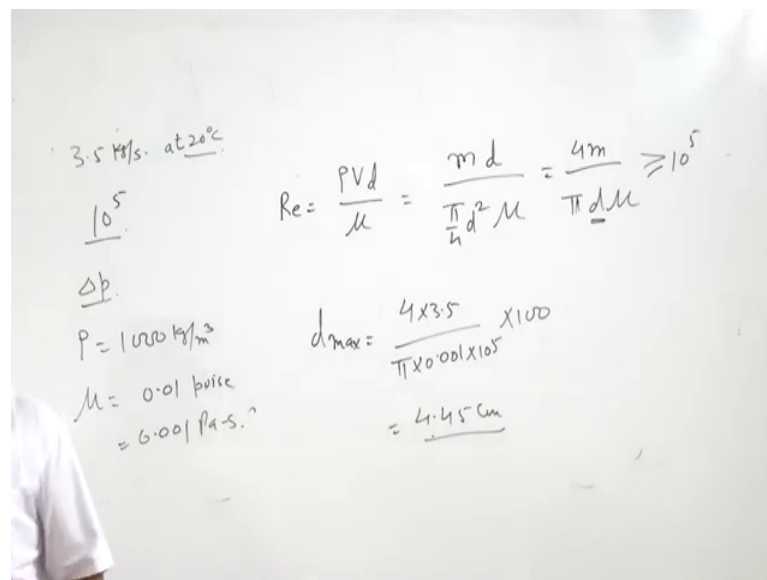

Example-4

A venturimeter is to be used to measure maximum flow rate of water of 3.5 kg/s at 20°C. The throat Reynolds number is to be at least 10^5 at these flow conditions. The upper scale limit is to be selected to correspond to the maximum flow rate. Determine the venturimeter size and the maximum range of differential pressure.

IT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | Prof. RAVI KUMAR | Department of Mechanical & Industrial Engineering | 5

Venturimeters are used for the flow measurement for metering the flow through a pipe. In this example a venturimeter is to be used to measure maximum flow rate of water of 3.5 kg per second that is a maximum flow rate 3.5 kg per second.

(Refer Slide Time: 23:37)

That is a mass flow rate of water at 20 degree centigrade. So, temperature is also given at 20 degree centigrade right.

The throat Reynolds number is to be at least 10^5 minimum Reynolds number at throat has to be 10^2 to 10^5 , it can be 10^6 , 10^7 , to 10^{10}

power 8, but minimum Reynolds number has to be maintained 10 to power 5, the upper scale limit is to be selected to corresponding to the maximum flow rate, determine the venturi size and the maximum range of differential pressure. So, venturi size and the maximum range for differential pressure.

So, it is a little design problem, is not totally numerical it is a little design problem because here some informations are to be required. For example, density of water density of water let us assume 1000 kg per meter cube density of the water. Viscosity of the water is 0.01 poise or 0.001 pascal seconds and Reynolds number here. Reynolds number here the Reynolds number are going to be $\rho V d$ by μ is the viscosity v is the velocity of water in the pipe, d is the diameter of the pipe, and ρ is the density of the pipe.

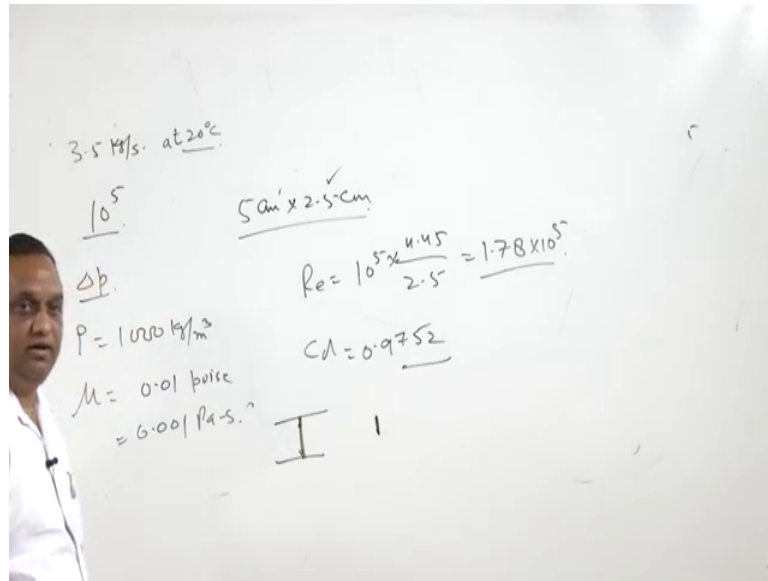

And we know that $V d$ sorry $V A$ and ρ is mass flow rate by continuity equation and A is π by 4 d square. So, Reynolds number can be written as mass flow rate multiplied by d divided by π by 4 d square μ . So, m by a will give the ρv . So, ρv is replaced by m . So, this will give 4 m divided by $\pi d \mu$ and that has to be greater than or equal to 10 raise to power 5.

Now, here mass flow rate is given 3.5 kg per second right μ is all also with us right and what is required d ? D we can find from here. So, d in order to find d that is d maximum is equal to 4 into 3.5 divided by π into 0.001 into 10 to power 5 into 100 is equal to 4.45 centimeters we have converted meter was normally the π diameter is the order of a few centimeters. So, we have converted meter into the centimeter it is 4.45 centimeters.

If you reduce the diameter the Reynolds number will increase, because not go by this formula mass flow rate. Because here if you reduce the diameter it appears the Reynolds number will reduce, but when you are reducing the diameter, velocity will increase if you go by this formula mass flow rate is constant. So, if you reduce the diameter Reynolds number will increase.

So, in any case we take the diameter is smaller than this, the Reynolds number will be more than 10 to power 5, but this is not a standard size in the market 4.445, it is difficult to get such type venturi. So, pipe into throat section if we go for the standard venturi it is could be going to be 5 centimeter in 2.5 centimeter.

(Refer Slide Time: 27:44)

So 5 centimeter into 2.5 centimeters and if you go for the throat diameter 2.5 centimeter definitely the Reynolds number will be higher than 10^5 right.

Now, with this selection of 2.5, the Reynolds number will be modified as 10^5 into $10^5 \times 2.5 / 0.001$, 1.78×10^5 . This condition is satisfied for this venturi coefficient of discharge is going to be 0.9752 for this Reynolds number 1.78×10^5 , this is 0.9752. Now we have coefficient of discharge a 1 area here which is which is the diameter of the pipe is 5 centimeter, area 2 of diameter of the pipe 2.5 centimeter, coefficient of discharge is already with us we can make use of this equation for the actual mass flow rate through the venturimeter that is $\rho C_d A_1 A_2 \sqrt{\frac{2(P_1 - P_2)}{\rho(A_1^2 - A_2^2)}}$ right.

(Refer Slide Time: 29:00)

$3.5 \text{ kg/s. at } 20^\circ\text{C}$
 10^5
 Δp
 $\rho = 1000 \text{ kg/m}^3$
 $\mu = 0.01 \text{ poise}$
 $= 0.001 \text{ Pa}\cdot\text{s}$

$$\dot{m} = \rho C_d \frac{A_1 A_2}{\sqrt{A_1^2 - A_2^2}} \sqrt{\frac{2g(P_1 - P_2)}{\rho g}}$$

$$P_1 - P_2 = 25.143 \text{ kPa}$$

I

G and g will be cancelled ok. So, this is the mass flowrate actual mass flowrate from this venturi meter, $A_1 A_2$ we can easily calculate because the diameter of 1 pipe is 5 centimeter another pipe diameter is 2.5 centimeters, the rest of the values are known, but we do not know the value of P_1 minus P_2 . So, this is only unknown in the entire equation and if you put the values with respective values, then you will be getting P_1 minus P_2 as 25.143 kilopascal.

So, whatever value you get from this equation divided by 1000, then you will be getting the pressure drop as 25.143 kilopascal right. So, this is the actual design of the venturi for the flow measurement, pipe diameter 5 centimeter venturi throat diameter is 2.5 centimeter and pressure drop is going to be 2.5143 kilopascal for the flow measurement of 3.5 kg per second. I hope you have enjoyed this course and in the following week you will have exam of the course, best of luck for examination.

Thank you.
