Lecture 06

Illustration for True and Engineering Strain

So welcome again to the new lecture of this course, Properties of Materials. So let us just briefly recap the previous lecture.

(Refer Slide Time: 00:22)

The image shows a digital whiteboard with handwritten notes. The notes are as follows:

Recap:

- Principal stresses $\sigma_1, \sigma_2, \sigma_3$
- $\sigma_p^3 - I_1 \sigma_p^2 - I_2 \sigma_p - I_3 = 0$
- $I_1, I_2, I_3 \rightarrow f(\sigma_{ij}, \tau_{ij})$
- $I_1 = \sigma_1 + \sigma_2 + \sigma_3$
- $I_2 = -\sigma_2 \sigma_3 - \sigma_3 \sigma_1 - \sigma_1 \sigma_2$
- $I_3 = +\sigma_1 \sigma_2 \sigma_3$
- Definitions of True & Engg Strain
- True strain \downarrow
 $\epsilon = \ln\left(\frac{L_f}{L_0}\right)$
- Engg strain \downarrow
 $e = \frac{L_f - L_0}{L_0}$
- $\epsilon = \ln(1 + e)$ (boxed)

The whiteboard interface includes a menu bar (File, Edit, View, Insert, Actions, Tools, Help), a toolbar with drawing tools, and a color palette. The slide number 13/29 is visible in the bottom right corner.

So in the previous lecture we looked that one calculation of principal stresses. σ_1 , σ_2 and σ_3 , which are basically from this equation $\sigma_p^3 - I_1 \sigma_p^2 - I_2 \sigma_p - I_3 = 0$, where I_1 , I_2 and I_3 are invariants, basically they are invariants of stresses independent of orientation of axis and σ , when you calculate this I_1 , I_2 , I_3 , which are given in terms of normal and shear stresses.

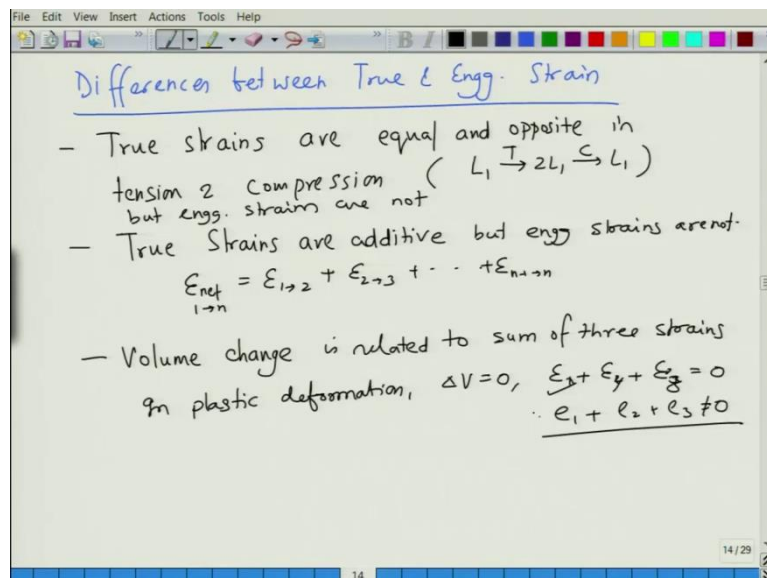

So I_1 , I_2 and I_3 are function of shear stresses σ and τ , and σ_x, σ_y or σ_z and τ_{ij} . You can calculate that three values of σ_p . And these three values of σ_p are nothing but magnitudes of σ_1 and σ_2 and σ_3 and σ , and I_1 , I_2 and I_3 are also related to these values. So I_1 is equal to $\sigma_1 + \sigma_2 + \sigma_3$. So you can cross check that. I_1 was also equal to $\sigma_x + \sigma_y + \sigma_z$.

So all these three values should match. I_2 was equal to minus of $\sigma_2 \sigma_3$, minus of $\sigma_3 \sigma_1$, minus of $\sigma_1 \sigma_2$. And I_3 was equal to minus of $\sigma_1 \sigma_2 \sigma_3$, sorry, plus $\sigma_1 \sigma_2 \sigma_3$ or write or alternatively just write it as $\sigma_1 \sigma_2 \sigma_3$.

2 and sigma 3. So these I values should match with the I values that you get from the products of summation of products of sigma x, sigma y, sigma z, as well as tau i j's.

So this is what we did and then we also look at the definitions of true and engineering strain. So true strain is $\ln(L_f / L_0)$ divided by L_0 , where engineering strain is given as $(L_f - L_0) / L_0$. And the relation between the two is $\epsilon = \ln(1 + e)$. And we also saw that this that there is a cross, so the values of epsilon and e, they correspond well with each other at very, very small strains, generally below 0.01, but the moment you go to higher strains there is a strong divergence and e values are very different as compared to epsilon values.

(Refer Slide Time: 03:19)

So now let us look at the other differences between the two strains and there are other differences, such as, first one is. So the first difference is true strains are equal and opposite in tension and compression. So let us say if you go from L_1 to $2L_1$, and then go back to L_1 , they will remain the same. So this is tension, this is compression. They will remain the same. We will see that in the examples. And then another difference is true strains are additive.

So in the first one, true strains are equal and opposite, but engineering strains are not. True strains are additive, but engineering strains are not. So which means epsilon net is equal to epsilon 1 to 2 let us say plus 2 to 3. So you go from one step to second step. First pass, second step to third step. Third pass and so on and so forth. And if you compute the sum, the sum will be equal to overall strain. Let us say if you go from $n-1$ to n , so this would be 1 to n . So this would sum. But engineering strain will not.

And the third is volume change is related to sum of three strains. As we will see in plastic deformation, ΔV is equal to 0, which means $\epsilon_1 + \epsilon_2 + \epsilon_3$ should be equal to 0 or $\epsilon_x + \epsilon_y + \epsilon_z$ should be equal to 0. But $\epsilon_1 + \epsilon_2 + \epsilon_3$ is not equal to 0. So there is an anomaly between these. So this obeys that principle of net, no net volume change, but this does not obey. So there is a problem there.

(Refer Slide Time: 06:24)

The image shows a whiteboard with handwritten notes comparing True Strain and Engineering Strain. At the top, it says "Example: Verify the tension/compression equivalence" and shows a process: $L_0 = 1\text{ m}$ (Tension) $\rightarrow L_1 = 2\text{ m}$, (Compression) $\rightarrow L_0 = 1\text{ m}$.

True Strain

- During tension: $\epsilon_t = \ln\left(\frac{2}{1}\right) = 0.693$
- During Compression: $\epsilon_c = \ln\left(\frac{1}{2}\right) = -0.693$

Engg. Strain

- During tension: $e_t = \frac{2-1}{1} = 1$
- During Compression: $e_c = \frac{1-2}{2} = -0.5$

Annotations on the whiteboard include:

- An arrow between the True Strain values labeled "Equal & opposite".
- An arrow between the Engg. Strain values labeled "not the same".
- A note "X not equivalent" with an arrow pointing to the Engg. Strain calculations.

So let us say, let us go to problem number one, let us say. So example number, first example is that let us verify, verify the tension compression problem, tension compression equivalence. So let us say we have L_0 of 1 meter, then we have L_1 of 2 meter, so L_0 goes to L_1 of 2 meter, then L_1 goes back to L_0 of 1 meter. So this is tension and this is compression, alright?

So if I examine the true strain, so during tension, ϵ_t will be equal to \ln of L_f divided by L_0 , which is 2 divided by 1, which is equal to 0.693. And during compression, ϵ_c will be equal to \ln of 1 divided by 2, L_f is. So in this case, it is going from 2 to 1. So 1 is the final length and 2 is the initial length and this will be minus of 0.693. So you can see that these are equal and opposite.

Now let us see the example of engineering strain. So during tension, I can see ϵ_t , sorry, e_t is equal to $L_f - L_0$ which is 2 minus 1 divided by 1 this is equal to 1, alright. During compression, e_c is equal to 1 minus 2 divided by 1 which is equal to 1 minus 2 divided by 2 which is equal to minus 0.5. So you can see that not only these are different, so these are not the same, because these are very large strains. These are not equivalent and

there is a problem. That is why true strain is a better measure of strain than the engineering strain.

(Refer Slide Time: 09:45)

The image shows handwritten notes on a whiteboard. At the top, a diagram shows a wire of initial length $L_0 = 1\text{ m}$. It is stretched in two passes: Pass 1 to $L_1 = 1.5\text{ m}$ and Pass 2 to $L_2 = 2\text{ m}$. The notes are divided into two columns: 'True Strain' and 'Engg Strain'.

True Strain:

- $\epsilon_{1 \rightarrow 2} = \ln \frac{1.5}{1} = 0.4055$
- $\epsilon_{2 \rightarrow 3} = \ln \frac{2}{1.5} = 0.2877$
- $\epsilon_{\text{total}} = 0.4055 + 0.2877 = 0.6932$ (marked as 'Equal')
- $\epsilon_{\text{total (direct)}} = \ln \frac{2}{1} = 0.6932$

Engg Strain:

- $e_{1 \rightarrow 2} = \frac{1.5 - 1}{1} = 0.5$
- $e_{2 \rightarrow 3} = \frac{2 - 1.5}{1.5} = 0.33$
- $e_{\text{total}} = 0.83$ (marked as 'not equal')
- $e_{\text{total (1-3)}} = \frac{2 - 1}{1} = 1$
- Conclusion: 'not additive'

Second example, let us take off, let us take that off additiveness. So let us say we have a piece of wire. This wire has initial length of 1 meter. We stretch it to L_1 is equal to 1.5 meter. So this is pass 1. It goes through pass 2 to L_2 is equal to 2 meters. So we can see that there is a net change from 1 to 2 meter in two passes. So let us calculate the strain at every step and the overall strain and compare the two.

So let us first look at the case of true strain. So when we calculate epsilon 1 to 2, it is ln of 1.5 divided by 1, which is 0.4055. And then we calculate epsilon 2 to 3, this is ln of 2 divided by 1.5 this is 0.2877. And as a result, epsilon total will be equal to 0.4055 plus 0.2877 this should be equal to 0.6932. And if I work out the epsilon total directly, then I go from 1 to 2 direct, so this is ln of 2 divided by 1 which is 0.6932 and these two are equal, which means true strains are additive.

Now let us look at the example of engineering strain. Engineering strain is epsilon 1 to 2 this is equal to, we are going from 1.5, 1 to 1.5, so it is 1.5 minus 1 divided by 1. So this is 0.5. So the second pass it is 2 minus 1.5 divided by 1.5. So this is equal to 0.33. So if I total them, sorry, this is e, not epsilon. My apologies. So e total will be equal to, did I write e earlier, so e total is equal to 0.83. And what is e total direct that is e 1 to 3, then it is 2 minus 1 divided by 1 which is 1. And we can see that these two are not equal, which means it is not additive. So this is the problem with the true engineering strain.

(Refer Slide Time: 13:27)

Example Volume Change

Initial dimensions L_{x_0} L_{y_0} L_{z_0}
 Final " L_{x_f} L_{y_f} L_{z_f}

Volumetric Strain

$$\frac{\Delta V}{V_0} (\text{Engg}) = \frac{V_f - V_0}{V_0} = \frac{L_{x_f} L_{y_f} L_{z_f} - L_{x_0} L_{y_0} L_{z_0}}{L_{x_0} L_{y_0} L_{z_0}}$$

$$\ln\left(\frac{V_f}{V_0}\right) (\text{True}) = \ln\left(\frac{V_f}{V_0}\right) = \ln\left(\frac{L_{x_f} L_{y_f} L_{z_f}}{L_{x_0} L_{y_0} L_{z_0}}\right)$$

When Δ Volume change is equal to zero, then
 $\epsilon_x + \epsilon_y + \epsilon_z = 0$ but $e_x + e_y + e_z \neq 0$ (H.W.)

Now let us look at the third another issue of volume change. So I will not do it completely. Let us say we have initial dimensions of L_x naught, L_y naught, L_z naught and the final dimensions are L_{x_f} , L_{y_f} , L_{z_f} . We need to calculate what is volumetric strain? Volumetric strain is ΔV divided by V naught. So if you calculate for engineering one, then it is V_f minus V naught divided by V naught.

So this is $L_{x_f} L_{y_f} L_{z_f}$ minus L_x naught L_y naught L_z naught divided by L_x naught L_y naught L_z naught. And if you calculate ΔV by V naught for true, this is \ln of V_f divided, sorry, this is V_f divided by V naught. So this will be \ln of L_f , L_{x_f} . Now I will leave it here. I will ask you to prove that when volume change is equal to zero, then one can see that ϵ_1 plus, ϵ_x plus ϵ_y plus ϵ_z is equal to 0, but the same is not true for. So I will leave it to you to prove that. So this is home work.

So what we have seen so far is basically we have looked at the differences between engineering and true strain. We have looked at the true strains are equal and opposite that we have proved using this. They are equivalent in tension and compression. True stresses are additive and engineering strains are not additive and volume change riddle that you have to do yourself that in the plastic deformation when volume change, and that volume change is equal to 0. It is represented by ϵ_x plus ϵ_y plus ϵ_z is equal to 0, but e_x plus e_y plus e_z is not equal to 0.

(Refer Slide Time: 17:06)

So now, this is what the first part of this lecture is. Now let us look at the concept of what we call as small strains and shear strains. So generally when a body deforms, so generally when a body deforms, let us say, this body when you deform it, this body may convert to a, let us say, a shape like this. But this the process through which this happens involves both translation and rotation of the elements or body parts you can say.

Now the strains have to be calculated in such a manner so that you are able to do them independently off rotation and translation. So you should look at the overall effect rather than getting into the integrities of translation and rotation. So a strain must overcome on a combined, the individual translation and rotation effects. So let us say we have a situation like this, in which let us say this is x and y axis.

We start with a body in this fashion. So we have these four points. C, D. These four points get move to, let us say, so let us say, this is A prime, B prime, C prime and D prime. Let us say, this length is initially dx, small lengths, this is dy. So let us say this point has moved by translation u in this direction and v in y direction. And the corresponding movement of this particular point from BC line is v plus $\frac{\partial v}{\partial x} dx$ into dy.

Similarly, the corresponding movement here is u plus $\frac{\partial u}{\partial y} dy$ into dx for a very small translation, and this is dx. So basically there is the extent of movement that we are having in x and y directions for... So you can see that this B point does not move just by, in this direction, just by v, it also moves by another small amount which is $\frac{\partial v}{\partial x} dx$. So you can see there is asymmetry. A point moves by different magnitudes as compared to a B point and so on and so forth. So let us calculate what the strains are.

(Refer Slide Time: 20:58)

Macroscopic Strain $\frac{\Delta L}{L_0} = \frac{A'D' - AD}{AD} = \frac{A'D'}{AD} - 1$

For very small strains,

$$\epsilon_{xx} = \left(\frac{\partial u}{\partial x}\right) dx/dx = \frac{\partial u}{\partial x}$$

$$\epsilon_{yy} = \left(\frac{\partial v}{\partial y}\right) dy/dy = \frac{\partial v}{\partial y}$$

Shear Strains

Here we need to work out strains in terms of angles θ with $AD \approx A'D'$ and $AB \approx A'B'$

$\gamma = \tan \theta = \frac{dx}{dy}$
for very small θ , $\gamma \approx \theta = \frac{\partial x}{\partial y}$

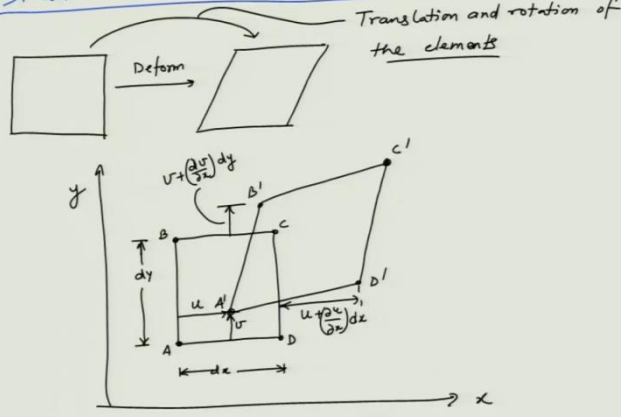

$$\left(\frac{\partial v}{\partial x}\right) dx/dx = \frac{\partial v}{\partial x}$$

$$\left(\frac{\partial u}{\partial y}\right) dy/dy = \frac{\partial u}{\partial y}$$

19 / 29

Small Strains & Shear Strains

Translation and rotation of the elements

18 / 29

So ϵ_{xx} , let us say we want to calculate, the macroscopic strain will be ΔL divided by L_0 and we can write this as $A'D' - AD$ divided by AD which is equal to $A'D'/AD - 1$. For very small values of L strains, sorry, for very small strains, one can write ϵ_{xx} as, so this is let us say, let us just write this as a macroscopic strain.

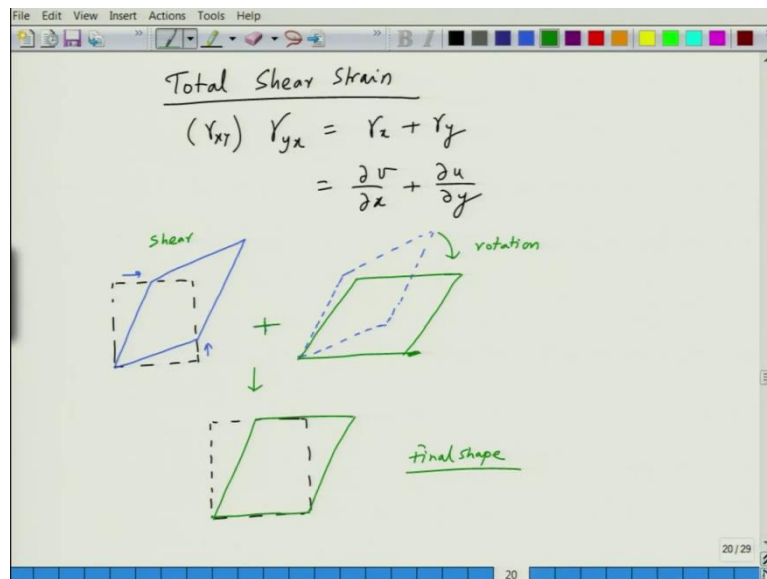

So ϵ_{xx} for a very small strain will be equal to $\frac{\partial u}{\partial x} dx$ divided by dx . So essentially it is $\frac{\partial u}{\partial x}$. ϵ_{yy} will be equal to $\frac{\partial v}{\partial y} dy$ divided by dy this will be equal to $\frac{\partial v}{\partial y}$, sorry, y . Now let us now see what the shear strains are. Shear strains are defined by, at the small level, so let us say if this is the angle θ , let us say

if this is the part dx, if this is the part dy, then tan theta is equal to dx divided by dy and for very small, small theta so this is gamma, shear strains represented by gamma.

So we can say gamma is equal to theta which is equal to dx by dy, let us say del x, del y. So using the same analogy for shear stresses, in terms of, so basically here, we need to work out strains in terms of angles between AD and AD prime, A prime, D prime, sorry, AD and AD prime and AB and let us say AB prime, so this is AD and this is AD prime. This is AB and this is AB prime. So if we do that, sorry, A prime, B prime it is not. Let me just correct it.

So it is AD and A prime D prime and AB and A prime B prime, I am sorry. So basically between this and that, between this and this. So if we now work out these strains, so we can write the first one as del v by del x into dx divided by dx, this will be equal to del v by del x. And the second one will be del u by del y into dy divided by dy this will be equal to del u by del y.

(Refer Slide Time: 24:58)

Macroscopic Strain $\frac{\Delta L}{L_0} = \frac{A'D' - AD}{AD} = \frac{A'D'}{AD} - 1$

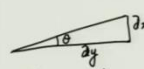

For very small strains,

$$\epsilon_{xx} = \left(\frac{\partial u}{\partial x}\right) dx/dx = \frac{\partial u}{\partial x}$$

$$\epsilon_{yy} = \left(\frac{\partial v}{\partial y}\right) dy/dy = \frac{\partial v}{\partial y}$$

Shear Strains

Here we need to work out strains in terms of angles θ 's
 $AD \approx A'D'$
 $AB \approx A'B'$

$\gamma = \tan \theta = \frac{dx}{dy}$
 for very small θ ,
 $\gamma \approx \theta = \frac{\partial x}{\partial y}$

$$\left(\frac{\partial v}{\partial x}\right) dx/dx = \frac{\partial v}{\partial x} \rightarrow \gamma_x$$

$$\left(\frac{\partial u}{\partial y}\right) dy/dy = \frac{\partial u}{\partial y} \rightarrow \gamma_y$$

So the total shear strain then in that case, which is gamma of y and x is equal to gamma of x. So this is gamma x, this is gamma y. So this will be equal to gamma x plus gamma y and this will be equal to del v by del x plus del u by del y, and this is also equivalent to let us say gamma xy. So basically what is happened is here, the process of rotation that is happened is, you start from let us say this shape, and then the first thing that you do is that, you have a shear and this allows.

So essentially it is come from here to here and then you create what we call as a, so you have this shape now. And this shape is now converted to which is the final transformation. So if you combine these two essentially, what you get is like this. So you start with this shape and you end up with the green one. So this is what we say is the shear and this will be rotation.

So this is shearing in this direction and this is rotating in this direction. So we are combining the process of shear and rotation to the overall deformation that we see in the final shape. So that is why these two shear strains have to be added, one in the x and other in the y. They give you the net shear strain for a two dimensional body.

(Refer Slide Time: 27:44)

For a 3-D body $u, v, w \rightarrow$ displacements along x, y, z directions.

$$\gamma_{yz} = \gamma_{zy} = \frac{\partial w}{\partial y} + \frac{\partial v}{\partial z}$$

$$\gamma_{xy} = \gamma_{yx} = \frac{\partial v}{\partial x} + \frac{\partial u}{\partial y}$$

$$\gamma_{zx} = \gamma_{xz} = \frac{\partial w}{\partial x} + \frac{\partial u}{\partial z}$$

$$\epsilon_{ij} = \begin{pmatrix} \epsilon_{xx} & \epsilon_{yz}(\epsilon_{xy}) & \epsilon_{xz}(\epsilon_{zx}) \\ \epsilon_{xy}(\epsilon_{yx}) & \epsilon_{yy} & \epsilon_{zy}(\epsilon_{yz}) \\ \epsilon_{xz}(\epsilon_{zx}) & \epsilon_{yz}(\epsilon_{zy}) & \epsilon_{zz} \end{pmatrix}$$

So let us say, for a three dimensional body now, so you have u, you have v, you have w, okay, u for x, v for y and w for z. So displacement is w and z direction, u is the displacement in x direction, and v is the displacement in. So these are displacements in along x, y and z directions. So if you now write them, then epsilon, epsilon yy we know is equal to del v by del y. So if I write gamma yz, so we do not need to actually write this. We just need to worry about gamma yz. Gamma yz is equal to gamma zy.

This is equal to del w divided by del y plus del v divided by del z. Similarly, I can write gamma xy which is equal to gamma yx, this is equal to gamma del v divided by del x plus del u divided by del y. And if you want to write gamma zx, sorry, what have I written, it should be gamma not delta. Gamma zx which is equal to gamma xz, this will be equal to del z by del x plus del w by del x and del u by del z. So these will be the three shear strains, six shear strains which will be basically for the three dimensional body.

So then you can write a shear stress tensor, shear strain tensor in the same way, epsilon xx, epsilon yx or xy, epsilon xz or epsilon zx and then you can write epsilon xy epsilon yx epsilon yy, here you will have epsilon zz, this will be epsilon zy or epsilon yz, this will be epsilon yz or epsilon zy, this will be epsilon yz or, sorry, zx, xz or zx and this will be zy. So this will be their strain tensor that we can write.

So we will stop here. We will come back to this and especially the transformational strain to different axis in the next class. And so what we have done is basically we have looked at the concept of shear strain, which is does not in solids deformation and we also look at, looked at

the differences between the true and engineering strain in this lecture. So thank you very much.
