Lecture – 12
Magnetic Hamiltonian, Heisenberg Model

Let us now discuss; how one gets a Magnetic Hamiltonian involving only spins. We are particularly talking about Ising kind of Hamiltonian or Heisenberg kind of Hamiltonians. Mainly, we would be talking about Ising Hamiltonians where the spin can only have either pointing up or down these are the two possible orientations. And let us see that how we can derive a Hamiltonian which we have introduced or rather we have talked about when we spoke on magnetism during our lectures.

(Refer Slide Time: 01:13)

Magnetic Hamiltonian
Addition of 2 $S = \frac{1}{2}$ particles.

Consider two particles with spins \vec{S}_1, \vec{S}_2 . The total spin angular momentum is,

$$\vec{S} = \vec{S}_1 + \vec{S}_2 \quad (\text{both are } s = \frac{1}{2})$$

Direct product space is 4-dimension. Use (s, m_s) basis for each

\vec{S} has eigenvalue S
 S_2 has eigenvalue m_s

Total space: $(s_1, m_{s_1}) \otimes (s_2, m_{s_2})$

So, we want to study magnetic Hamiltonian and a derivation of a magnetic Hamiltonian would require that we know the addition of spins or so, say addition of 2 spins 2 and these are spin half particles. So, we have 2 spin half particles and we would see that how one actually add the spin vectors. So, let us consider two particles with spin vectors S_1 and S_2 , the total angular momentum I mean what I mean by angular momentum is that the total spin angular momentum is S equal to S_1 plus S_2 . Where S_1 and S_2 's are the spin vectors for the two particles that we are considering so, just to remind you that both are spin half.

Now, the direct product space is that consists of it is of 4 dimensions. So, that direct product space is 4 dimensional and we can use the basis use $S_m s$ basis for each. So, what I mean by that is that the eigenvalue for the spin operator S is has eigenvalue s and s_z has eigenvalue m_s . So, we can form the basis of each of the particles by this $S_m s$ and the total space will be product of such to such $S_m s$'s that is $s=1$. So, total product total space is $S=1, m_s=1$ and $S=2, m_s=2$.

(Refer Slide Time: 04:27)

$$\begin{array}{l}
 m_s = \pm \frac{1}{2} \hbar \\
 \left. \begin{array}{l} |\uparrow\rangle \quad |\downarrow\rangle \\ +\frac{\hbar}{2} \quad -\frac{\hbar}{2} \\ (\alpha) \quad (\beta) \end{array} \right\} \begin{array}{l} \text{Spin space} \\ \alpha(1)\alpha(2), \alpha(1)\beta(2), \beta(1)\beta(2) \\ |\uparrow\uparrow\rangle, |\uparrow\downarrow\rangle, |\downarrow\uparrow\rangle, |\downarrow\downarrow\rangle \end{array} \begin{array}{l} \text{--- one option} \\ \text{--- other option} \end{array} \\
 \text{choose} \\
 M_s = m_{s1} + m_{s2} = 1, 0, 0, -1 \\
 S = s_1 + s_2 = 0, 1 \\
 \text{For } S=0 \quad \chi_{00} = \frac{1}{\sqrt{2}} [|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle] \begin{array}{l} \text{Singlet wave} \\ \text{function.} \\ \text{Antisymmetric.} \end{array} \\
 \text{For } S=1 \quad \begin{array}{l} \chi_{11} = |\uparrow\uparrow\rangle \\ \chi_{10} = \frac{1}{\sqrt{2}} [|\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle] \\ \chi_{1-1} = |\downarrow\downarrow\rangle \end{array} \left. \begin{array}{l} \\ \\ \end{array} \right\} \begin{array}{l} \text{Triplet states} \\ \text{Symmetric} \end{array}
 \end{array}$$

And let the since we have for each one of them so m_s is equal to plus minus half \hbar cross; so, let us represent the states by up and down. So, each of these half \hbar will correspond to say a up and this minus half will correspond to minus half \hbar cross. So, this \hbar cross over 2 and this is minus \hbar cross over 2 and hence we will have we can write it in two ways. So, the space the spin space or the direct product space is either you call it alpha 1. So, maybe this is called as a alpha and this is called as a beta or so it is alpha 1 alpha 2 which means both are in up spin states, alpha 1 beta 2 means one of them in up spin the other in down spin state.

And alpha 2 beta 1 the first one is in the down and the second one is in up or both of them are in the down. And this is one option where as the other option is that we can write it as up up as the states, up down and down up and down down. So, this is other option and we can simply choose one of them, but let us choose this option in order to write the wave function for the or and I mean to discuss this problem of 2 spins.

So, what is the total value of M_S which is $m_{s1} + m_{s2}$, m_{s2} which can take value 1, 0, 0, minus 1; 1 when they both add up half plus half and this is when half minus half this is minus half half and this is minus half minus half. And the total spin quantum number S which is equal to $s_1 + s_2$, which can take value 0 and 1 ok. So, for s equal to 0 for s equal to 0; we have there just 1 eigen function and that eigen function let us write it with a form which is χ_{00} which is equal to $1/\sqrt{2}$.

And I have a up down minus a down up. So, this is; the this is called as a singlet wave function and this is antisymmetric, what I mean by antisymmetric is the following; that you have two particles. So, the first one is in upstate the second one is in downstate, here the second one the first one is in downstate and the second was in is in upstate. And now if you interchange up to down one gets a negative sign. So, this is that is why it is called as a antisymmetric and for s equal to 1 we would need so for s equal to 1 we will have three combination because, we will have to take care of χ_{11} which will be simply a up up state χ_{10} which will simply be a combination of up down plus a down up and a χ_{1-1} which is equal to a down down state.

Now, all these are called as triplet and triplet states because they are three in number and one can easily check that they are symmetric because, if the first particle is written swapped with the second particle the wave function remains the same. So, these are the states or the wave functions for 2 particles both spin half and for a system consisting of or comprising of 2 spin half particles and all possible combinations have been taken. We get 4 states and those 4 states are one singlet and three triplet states, the singlet state is a antisymmetric with respect to the change in the position of the particle and the triplet states are symmetric with respect to the change in the position of the particle.

So, these are the states, but what about the eigenvalues, because in order to solve a full quantum mechanical problem we both we need the both the information on the eigenvalues and the eigen functions.

(Refer Slide Time: 10:21)

$$\begin{aligned}
 & |\uparrow\uparrow\rangle, |\downarrow\uparrow\rangle, |\uparrow\downarrow\rangle, |\downarrow\downarrow\rangle \text{ - basis of a 2 particle } (s=\frac{1}{2}) \text{ system} \\
 & \text{They are eigenstates of } \vec{S}_1^2, \vec{S}_2^2, S_{1z}, S_{2z}. \\
 & \text{Total spin, } S = 0, 1 \\
 & S_z |\uparrow\uparrow\rangle = (S_{1z} + S_{2z}) |\uparrow\uparrow\rangle = \hbar |\uparrow\uparrow\rangle; S_z |\uparrow\downarrow\rangle = 0 \\
 & S_z |\downarrow\uparrow\rangle = 0, S_z |\downarrow\downarrow\rangle = -\hbar |\downarrow\downarrow\rangle \\
 & \text{Furthermore, } \vec{S}^2 = (\vec{S}_1 + \vec{S}_2)^2 = \vec{S}_1^2 + \vec{S}_2^2 + 2\vec{S}_1 \cdot \vec{S}_2 \\
 & \vec{S}^2 |\uparrow\uparrow\rangle = \hbar^2 \frac{1}{2}(\frac{1}{2}+1) + \hbar^2 \frac{1}{2}(\frac{1}{2}+1) + 2\vec{S}_1 \cdot \vec{S}_2 \\
 & \vec{S}_1 \cdot \vec{S}_2 = S_1^x S_2^x + S_1^y S_2^y + S_1^z S_2^z \quad \begin{aligned} S_+ &= S_x + iS_y \\ S_- &= S_x - iS_y \end{aligned} \\
 & = \frac{1}{2}(S_1^+ S_2^- + S_1^- S_2^+) + S_1^z S_2^z
 \end{aligned}$$

So, let us see that say all these 3 states so, now, will talk about the eigenvalues these states are up up, up down, down up and down down. And so, this forms the basis of the problem of a 2 particle problem, 2 particle spin half system. So, they are eigen states of S^2 , S_z , S_{1z} and S_{2z} . So, the total spin S can be 0 or 1 ok.

So, now we can see the how these total spin operators act on those each of the states. So, the total spin operator which is S_z which is equal to S_{1z} plus S_{2z} that acting this state acting on or let us write it here as well. So, S_z acting on the up up, state up up this will give me S_{1z} will only act on the first spin on the left and S_{2z} will act on the spin on the right. So, this will give me \hbar cross by 2 for each one them and I will get a \hbar cross by 2 and a up up.

So, as we have said that these are eigen states of these operators so, I get an eigenvalue equation which is S_z acting on a up up state gives me \hbar cross by 2 as a eigenvalue and returns me the up up state is well. Similarly for S_z acting on up down would give me 0 because S_{1z} will give me a plus \hbar cross by 2 and S_{2z} will give me a minus \hbar cross by 2 and similarly, we will also have S_z acting on the down up state should also give me 0. And S_z now acting on the down down state will give me a minus \hbar cross sorry this is a minus \hbar cross by 2 for each. So, this should be simply \hbar cross.

So, this is for each one of them there is an \hbar cross by 2. So, there is there are 2 \hbar cross by 2 which make as \hbar cross. So, S_z on down down will give me a minus \hbar cross and so on.

So, these are the eigenvalues of these S_z operator and what about so further more we have a S^2 which is equal to S_1^2 which is $S_1^2 + S_2^2$ whole square which is equal to $S_1^2 + S_2^2 + 2 S_1 \cdot S_2$ and S_1 and S_2 will commute with each other because they pertain to different particles.

So, S_1^2 will be $\frac{h^2}{4}$ so, it is half into half plus 1, half into half plus 1 this acting on so, S^2 acting on any of these states. So, say we will talk about up up say for example. So, this is equal to half into half plus 1 sorry if S into S plus 1. So, that is this and then again for the S_2^2 this will be half into half plus 1 now we of course, do not know the what is $2 S_1 \cdot S_2$. So, we will leave it for the moment and let us see that what we can do for the $S_1 \cdot S_2$.

So, $S_1 \cdot S_2$ if you see it is equal to $S_1 x S_2 x + S_1 y S_2 y + S_1 z S_2 z$. Now, if you introduce this ladder operators for the spins so, S_+ can be written as $S_x + i S_y$ and S_- can be written as $S_x - i S_y$. Now this will give me S_+ ; plus S_2 minus plus S_1 minus S_2 plus and then there will be a factor of half there and plus $S_1 z S_2 z$ so, this is $S_1 \cdot S_2$.

(Refer Slide Time: 16:26)

$$\begin{aligned} \vec{S}^2 |\uparrow\uparrow\rangle &= \left[\frac{3}{4} \hbar^2 + \frac{3}{4} \hbar^2 + 2 \left(\frac{\hbar^2}{2} \right) \right] |\uparrow\uparrow\rangle \\ &= 2 \hbar^2 |\uparrow\uparrow\rangle \\ \vec{S}^2 |\downarrow\downarrow\rangle &= 2 \hbar^2 |\downarrow\downarrow\rangle \end{aligned}$$

States $|\uparrow\uparrow\rangle$ and $|\downarrow\downarrow\rangle$ have total spin $S=1$, $m_s = \pm 1$
 $m_s = 0$ state is obtained by the application of S_- on $|\uparrow\uparrow\rangle$
(or S_+ on $|\downarrow\downarrow\rangle$)

$$S_- |\uparrow\uparrow\rangle = (S_1^- + S_2^-) |\uparrow\uparrow\rangle = \hbar [|\downarrow\uparrow\rangle + |\uparrow\downarrow\rangle]$$

$$\frac{1}{\hbar} S_- |\uparrow\uparrow\rangle = \frac{1}{\sqrt{2}} [|\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle] \Rightarrow \text{Correspond to } S_z = 0.$$

\Rightarrow Triplet states

And hence what we can do is that we can see that S^2 acting on a up up which we have already saw that the first term gives three-fourth h^2 second term gives three-fourth h^2 as well.

Now, we have a $2 S_1 \cdot S_2$, now for the up up state this will raise the spin and hence it will be 0 because up is the maximally aligned state and though S_2 minus can give you a non zero contribution, but S_1 plus will give 0. And similarly S_2 plus will give 0 and that is why these 2 terms do not contribute and that simplifies the problem and then we are left with $S_1 z S_2 z$ for which we know the operation. So, that is why we have done this and this is 2 into \hbar cross by 2 and this whole thing and this whole thing multiplied or rather acted upon by this.

So, it is eigenvalue equation and this is if you simplify it becomes equal to $2 \hbar$ cross square up up and so on. And similarly for the down down is well one gets the same answer by doing the same technique one gets this as so on these acting on the down down state will give us a $2 \hbar$ cross square and a down down. And so, they have so, these states up up and down down have total spin S equal to 1 and m_s equal to plus minus \hbar cross ok.

But of course, S equal to 1 should have three states; which are equal to m_s plus minus \hbar and 0. So, the third state so, m_s equal plus minus \hbar is there. So, m_s equal to 0 state is obtained by a particular operation. So, by the application of S minus on up up state let us see how one gets it or you can also consider or S plus on the down down states. So, S plus S minus on the up up state gives me S_1 minus plus a S_2 minus on the up up state which gives me so, S_1 minus will lower this spin. And now this is something that you should have done in quantum mechanics, this gives me an eigenvalue which is these are not eigen states of up up.

But it will operate on this and give me this S_1 will give me a \hbar cross and will give me up down, sorry it will be a down up the first one will lower. So, it is a down up plus and up down S_2 will lower the other one with an eigenvalue which is given by \hbar cross.

And so, 1 over \hbar cross S minus; up up is nothing, but 1 by root 2 which comes as a normalization factor up down plus down up does not matter we have written down the second term ahead of the first term. And this will correspond to S_z equal to 0 so, these three will be called as the triplet states. And so, the singlet states are of course, the which corresponds to so, these are the triplet states.

(Refer Slide Time: 21:15)

$$\begin{aligned}
 &\text{Singlet state } S=0, m_s=0 \\
 &|\chi_{00}\rangle = |00\rangle = \frac{1}{\sqrt{2}}(|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle) \\
 &S_z |00\rangle = \left[\frac{3}{2}\hbar^2 - 2\left(\frac{\hbar}{2}\right)^2 - \hbar^2 \right] |0,0\rangle = 0 |0,0\rangle \\
 &\text{Construction of a magnetic Hamiltonian} \\
 &\vec{S}^2 = \vec{S}_1^2 + \vec{S}_2^2 + 2\vec{S}_1 \cdot \vec{S}_2 \\
 &\text{Eigenvalue of } \vec{S}^2 = \frac{3}{2}\hbar^2 + 2\vec{S}_1 \cdot \vec{S}_2 \\
 &\text{So for the Singlet state, } S=0 \Rightarrow \vec{S}_1 \cdot \vec{S}_2 \Rightarrow \text{has eigenvalue} \\
 &\quad -\frac{3}{4}\hbar^2
 \end{aligned}$$

So, the two that is coming over here with spin S equal to 1 and m_s equal to one which is here and the other one comes from here so, these are the three states. And now we will just look at the singlet state. So, which corresponds to S equal to 0 m_s equal to 0, let us just call it as we can call it as χ_{00} or we can also use a notation which is like $|00\rangle$, which is equal to a half up down minus down up.

So, why is it a singlet state? So, S_z acting on this $|00\rangle$ will give me a 3 by 2. So, it is $S_1 z$ plus $S_2 z$ which will act on this it will be a 3 by 2 \hbar^2 minus 2 into \hbar^2 minus 2 square minus \hbar^2 acting on $|00\rangle$ and it will give me a $|00\rangle$. So, which means that m_s value of this is equal to 0 and this has S equal to 0. So, we have found out all the four eigen states of this of these 2 particle problem. So, let us now; look at the spin Hamiltonian consisting of these, if you want to construct a Hamiltonian only consisting of these two spins which is like a as I said as like a Ising Hamiltonian or a Heisenberg Hamiltonian if S has a full rotational symmetry.

So, let us just discuss the construction of a magnetic Hamiltonian. So, we have S^2 which is equal to S_1^2 plus S_2^2 plus a $2 S_1 \cdot S_2$. Now the eigenvalue of eigenvalue of S^2 is equal to 3 by 2 \hbar^2 as we have discussed that 3 by 3 coming comes from 2 terms of 3 by 4 \hbar^2 each of S_1 and S_2 and plus a $2 S_1 \cdot S_2$. So, for the singlet state that is S equal to 0, we will have to put S equal to 0 the $S_1 \cdot S_2$ has an eigenvalue, which is equal to minus half minus 3 4th \hbar^2 .

Because this is equal to 0, if you put the right hand side equal to 0 the $S_1 \cdot S_2$ will have an eigenvalue which is half of a minus of half of 3 by 2 \hbar cross square which is minus 3 by 4 \hbar cross square.

(Refer Slide Time: 25:36)

For the triplet state, $S=1$

$$1(1+1)\hbar^2 = \frac{3}{2}\hbar^2 + 2\vec{S}_1 \cdot \vec{S}_2$$

$$\frac{2\hbar^2 - \frac{3}{2}\hbar^2}{2} \Rightarrow \vec{S}_1 \cdot \vec{S}_2 \text{ for the triplet state.}$$

$\frac{1}{4}\hbar^2$ is the e-value for $\vec{S}_1 \cdot \vec{S}_2$

e-value of $\vec{S}_1 \cdot \vec{S}_2$	Singlet	Triplet
	$-\frac{3}{4}\hbar^2$	$\frac{1}{4}\hbar^2$

Whereas for the triplet state which corresponds to S equal to 1. So, that will have 1 into 1 plus 1 \hbar cross square for the left hand side, which is equal to a 3 by 2 \hbar cross square and plus twice of $S_1 \cdot S_2$ so, this is equal to 2. So, 2 \hbar cross square minus 3 half \hbar cross square divided by 2 is the eigenvalue for $S_1 \cdot S_2$ for the triplet state.

So, this is equal to 2 minus 3 half is just half. So, this is equal to one-fourth \hbar cross square. So, one-fourth \hbar cross square is the eigenvalue in short e value I am writing for the operator $S_1 \cdot S_2$ in the for a 2 particle problem. So, let us just summarize this quick result. So, for singlet states $S_1 \cdot S_2$ so this is singlet and triplet. So, this singlet one has minus 3 by 4 \hbar cross square and this is one-fourth \hbar cross square. So, this is the eigenvalue of $S_1 \cdot S_2$.

(Refer Slide Time: 27:30)

Write down a Hamiltonian,

$$H = \frac{1}{4}(E_s + 3E_t) - (E_s - E_t) \vec{S}_1 \cdot \vec{S}_2$$

E_s : energy of the singlet state
 E_t : energy of the triplet state

$$H |00\rangle = \left[\frac{1}{4}(E_s + 3E_t) - (E_s - E_t) \vec{S}_1 \cdot \vec{S}_2 \right] |00\rangle$$

$$E_s = -\frac{3}{4} \hbar^2, \quad E_t = \frac{1}{4} \hbar^2$$

$$H |0,0\rangle = -\frac{3}{4} \hbar^2 |0,0\rangle$$

$$H \begin{Bmatrix} |\uparrow\uparrow\rangle \\ |\downarrow\downarrow\rangle \\ \frac{1}{\sqrt{2}}(|\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle) \end{Bmatrix} = \frac{1}{4} \hbar^2 \begin{Bmatrix} |\uparrow\uparrow\rangle \\ |\downarrow\downarrow\rangle \\ \frac{1}{\sqrt{2}}(|\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle) \end{Bmatrix}$$

Now, if we write down a Hamiltonian, which is H equal to one-fourth E_s plus 3 E_t I will tell you what these are E_s minus E_t $S_1 \cdot S_2$. We have written it in a particular way a this term where E_s is the energy of the singlet state and E_t is the energy of the triplet state.

And why have we written it in this fashion is that H acting on the singlet state which is $|0,0\rangle$ will be simply equal to this one-fourth E_s plus 3 E_t and E_s minus E_t $S_1 \cdot S_2$ acting on $|0,0\rangle$. We can skip the comma in between so that is the singlet state. So, with E_s equal to minus 3 by 4 \hbar^2 and E_t equal to one-fourth \hbar^2 one can simply check that H of $|0,0\rangle$ will give me a minus 3 by 4 \hbar^2 $|0,0\rangle$.

And similarly H acting on either of these; up up states or down down states or up down plus down up states all those multitude of you know down down or up down plus down up, up down plus down up state with a normalization will give me a 1 by 4 \hbar^2 and these states that we have written such as up up, down down, up down plus down up.

So, that says that we have arrived at a Hamiltonian which is which gives us for a 2 particle problem which gives us the correct energy eigenvalues for 2 spin half particles for a system of 2 spin half particles and this is that Hamiltonian.

(Refer Slide Time: 30:56)

If we redefine the zero of the energy, we may omit the constant $\left(\frac{E_s + 3E_t}{4}\right)$ which is common to all the 4 states, then we can write down a Spin Hamiltonian as,

$$H = J \vec{S}_1 \cdot \vec{S}_2 \quad J = E_s - E_t$$

$$H = -J \sum_{\langle ij \rangle} \vec{S}_i \cdot \vec{S}_j \quad \text{--- (1)}$$

If J is positive, (1) favours parallel arrangement (ferromagnetism)
 If J is negative, (1) favours antiparallel arrangement (antiferromagnetism)

Now you can see that if you if we redefine the zero of the energy we may omit the constant $E_s + 3E_t$ by 4 which is common to all the states all the all the 4 states. Then we can write down a Spin Hamiltonian, Spin Hamiltonian as H equal to J into S_1 dot S_2 , where J is nothing, but the difference between the singlet and the triplet energies here of course, we have the singlet energy to be a lower which is equal to minus 3 by 4 h cross square. And E_t being a 1 4th h cross square so, J will be negative.

Now if we say that such Hamiltonians can be written for n particles with a pair wise interaction between the particles, then we can write a generic Hamiltonian for a magnetic system or spin half system. We can extend it to a spin having any values it should be then it is a J and then there is a S_i dot a S_j it is i and j . It is between the neighboring sides and this is Heisenberg Hamiltonian if S has a full rotational symmetry.

And it is just the Ising Hamiltonian if S is taken as plus minus half, but; however, it gives magnetic properties of the magnetic system such as antiferromagnet or ferromagnet. And of course, its if J is positive now we are not considering, restricting ourselves to only 2 particles were we know that J is negative, but we also consider go ahead and consider J to be positive is well.

So, if J is positive in this particular model in this Hamiltonian given by 1, 1 favours we can write it with a minus sign putting a minus sign from outside. Then this favours parallel arrangement of spins and which are essential for ferromagnetism. And if J is

negative then 1 favours antiparallel arrangement. And it is antiferromagnetism is, we have seen these phenomena from a purely electronic model which is Harvard model, but; however, we have also got an exposed to this kind of spin only models which are there.

So, if J is positive then the energy is lowered if the S_i dot S_j that is the S_i and S_j they point the spin vectors point in the same direction. Which are in a sense we talk about ferromagnetism whereas, if J is negative then; that means, that the whole energy would be negative if S_i and S_j are antiparallely aligned which are the features of antiferromagnetism.

(Refer Slide Time: 35:49)

Compared with magnetic dipole-dipole interaction,

$$U = \frac{1}{r^3} \left[\vec{m}_1 \cdot \vec{m}_2 - 3(\vec{m}_1 \cdot \hat{r})(\vec{m}_2 \cdot \hat{r}) \right]$$

$$H = J \sum_{\langle ij \rangle} \vec{S}_i \cdot \vec{S}_j \quad i, j \text{ are nearest neighbours}$$

$$= \sum_{\langle ij \rangle} J_{ij} \vec{S}_i \cdot \vec{S}_j$$

And so, this can be actually compared with the magnetic dipolar interaction like this which is 1 over r cube and it is a m_1 dot m_2 so, these are the two magnetic moments. And these are related this you are familiar in the context of classical electromagnetic theory. And the relative distance where the relative distance between m_1 and m_2 are involved, but here we have a purely spin Hamiltonian which neglects all special symmetries. Now this is H written as $J S_i$ dot S_j has there are a large number of approximation that are going on.

Namely i, j are nearest neighbors one does not have to be one can include; or longer than nearest neighbor that is next to next nearest neighbor interactions is well. And we can also write this inside the J to be inside and it does not have to be constant and it can

depend from a one bond to another. And so, these are these are possible Hamiltonians and they have all been explored in the context of spin systems.
