Lecture - 40
Input-Output Relation

Welcome to lecture 8 of module 3. This is lecture number 29 of the course. In this lecture, we will see how quantum noise, quantum Langevin noise in particular, affects the optical mode of a Fabry-Perot cavity. And this will lead us to the very famous input-output relation. And this relation is going to be extremely useful for our discussion on quantum cavity optomechanics. So let us begin.

(Refer Slide Time: 01:02)

Assume the bath to be a collection of N independent Quantum Harmonic Oscillators at temperature T .

$$\rho_{th} = \sum_{n=0}^{\infty} P_n |n\rangle\langle n|$$

$$\langle \hat{A} \rangle = \text{Tr}(\hat{\rho} \hat{A})$$

Hence,
$$P_n = \frac{e^{-E_n/k_B T}}{\sum_{n=0}^{\infty} e^{-E_n/k_B T}}$$

$$E_n = \left(n + \frac{1}{2}\right) \hbar \omega \approx n \hbar \omega$$

In the last class, we started discussing the quantum counterpart of the classical Langevin noise. In this regard, we have assumed the bath to be a collection of N independent quantum harmonic oscillator at some finite temperature T . As we have to calculate the expectation value of various operators, we needed to know the appropriate density operator as we know that the expectation value of any operator A is given by trace of rho into the operator.

So we first wrote down the density operator in the so called number state basis where this guy P_n is the probability.

(Refer Slide Time: 01:54)

- Average phonon number:

$$\langle \hat{b}^\dagger \hat{b} \rangle = n(\omega_m) = \frac{1}{e^{k\omega_m/k_B T} - 1}$$

And we calculated the average phonon number.

(Refer Slide Time: 01:59)

- Position - position correlation for an ensemble of N-harmonic oscillators

$$\langle \hat{a}_i \hat{a}_j \rangle$$

$$\rho_{th} = \left(\sum_{n_1=0}^{\infty} P_{n_1} |n_1\rangle \langle n_1| \right) \left(\sum_{n_2=0}^{\infty} P_{n_2} |n_2\rangle \langle n_2| \right) \dots \left(\sum_{n_N=0}^{\infty} P_{n_N} |n_N\rangle \langle n_N| \right)$$

$$\rho_{th} \equiv \sum \prod P_{n_k} | \{n_k\} \rangle \langle \{n_k\} |$$

After that we worked out the position-position correlation function for an ensemble of N-harmonic oscillator. And first we started by calculating the expectation value of product of two position operators for i-th and the j-th oscillator.

(Refer Slide Time: 02:22)

$$\{n_k\}^k$$

$$\hat{q}_i = a_{i0} \left(\hat{b}_i + \hat{b}_i^\dagger \right), \quad a_{i0} = \sqrt{\frac{\hbar}{2m_i \omega_i}}$$

$$\hat{q}_j = a_{j0} \left(\hat{b}_j + \hat{b}_j^\dagger \right)$$

$$a_{j0} = \sqrt{\frac{\hbar}{2m_j \omega_j}}$$

We have expressed the position coordinate in terms of the quantum annihilation and creation operators.

(Refer Slide Time: 02:28)

$$\langle \hat{q}_i \hat{q}_j \rangle = \sum_{\{n_k\}} \prod_k P_{n_k} a_{i0} a_{j0} \left[\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)} \right] \delta_{ij}$$

$$= \sum_{n_i} P_{n_i} a_{i0} a_{j0} \left[\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)} \right] \delta_{ij}$$

Finally, summing

$$\sum_{i,j=1}^N \langle q_i q_j \rangle = \sum_{i,j}^N \sum_{n_i} a_{i0} a_{j0} P_{n_i} \left[\sqrt{n_i n_j} + \sqrt{(n_i+1)(n_j+1)} \right] \delta_{ij}$$

$$= \sum \sum a_{i0}^2 P_{n_i} (2n_i + 1)$$

And thereby, we have arrived at the expression for the expectation value of q_i and q_j .

And finally summing it over the all oscillators, we got the expression.

(Refer Slide Time: 02:42)

$$n(\omega_i) = \frac{1}{e^{\hbar\omega_i/k_B T} - 1}$$

$$\sum_{i,j}^N \langle \hat{q}_i \hat{q}_j \rangle = \sum_i q_{i0}^2 \coth\left(\frac{\hbar\omega_i}{2k_B T}\right)$$

$$[\hat{q}_i, \hat{p}_j] = i\hbar \delta_{ij}$$

$$\sum_{i=1}^N (\hat{p}_i^2 + \frac{1}{2} m \omega_i^2 \hat{q}_i^2)$$

And we expressed it in the in this particular form here.

(Refer Slide Time: 02:46)

$$[\hat{q}_i, \hat{p}_j] = i\hbar \delta_{ij}$$

$$\hat{H} = \frac{\hat{p}^2}{2m} + \frac{1}{2} m \omega_m^2 \hat{z}^2 + \sum_{i=1}^N \left(\frac{\hat{p}_i^2}{2m_i} + \frac{1}{2} m_i \omega_i^2 \hat{q}_i^2 \right) - \hat{z} \sum_{i=1}^N c_i \hat{q}_i + \hat{z}^2 \sum_{i=1}^N \frac{c_i^2}{2m_i \omega_i^2}$$

$$\rightarrow m \ddot{\hat{z}} + m \omega_m^2 \hat{z} + m \gamma_m \dot{\hat{z}} = \hat{\xi}(t)$$

Then we wrote down the quantum mechanical Hamiltonian for the bath oscillator system. Here the Hamiltonian has exactly the same form as that of the classical one. Only thing is that this variable position and the momentum variable are the operators and they has to satisfy the commutation relation as defined in this equation.

(Refer Slide Time: 03:14)

$$- \hat{q} \sum_{i=1}^N c_i \hat{q}_i + \hat{q}^2 \sum_{i=1}^N \frac{c_i^2}{2m_i \omega_i^2}$$

$$\rightarrow m \ddot{\hat{z}} + m \omega_m^2 \hat{z} + m \gamma_m \dot{\hat{z}} = \hat{\xi}(t)$$

Quantum Langevin noise

$$\hat{\xi}(t) = \sum_{i=1}^N c_i \left[\hat{q}_i(0) \cos \omega_i t + \frac{\hat{p}_i(0)}{m_i \omega_i} \sin \omega_i t \right]$$

So using Heisenberg equation of motion, we can get an equation analogous to the classical Langevin equation where this classical Langevin noise is now represented by this operator. And it has also exactly the same form in the limit when the bath oscillator coupling is assumed to be weak.

(Refer Slide Time: 03:36)

$$\hat{\xi}(t) = \hat{\xi}^\dagger(t)$$

$$\hat{\xi}(t) \hat{\xi}(0) \neq \hat{\xi}(0) \hat{\xi}(t)$$

$$\langle \hat{\xi}(t) \hat{\xi}(t') \rangle$$

$$= \sum_{ij} c_i c_j \left[\langle \hat{q}_i(0) \hat{q}_j(0) \rangle \cos \omega_i t \cos \omega_j t' \right. \\ \left. + \frac{\langle \hat{q}_i(0) \hat{p}_j(0) \rangle}{m_j \omega_j} \cos \omega_i t \sin \omega_j t' \right. \\ \left. + \frac{\langle \hat{p}_i(0) \hat{q}_j(0) \rangle}{m_j \omega_j} \sin \omega_i t \cos \omega_j t' \right]$$

We find that this is very easy to see that this Langevin noise operator is Hermitian and because of the fact that these are quantum operators, so $\xi(t)$, $\xi(0)$ is not equal to $\xi(0)$, $\xi(t)$. That means the order, time order also this depends. We calculated the expectation value of this product of this quantum Langevin noise which is the auto correlator.

(Refer Slide Time: 04:09)

$$\bullet \langle \hat{x}(t) \hat{x}(t') \rangle = \sum_{i=1}^N \frac{\hbar c_i^2}{2m_i \omega_i} \left[\coth\left(\frac{\hbar \omega_i}{2k_B T}\right) \cos \omega_i (t-t') - i \sin \omega_i (t-t') \right]$$

$$\bullet \boxed{J(\omega) = \pi \sum_{i=1}^N \frac{c_i^2}{2m_i \omega_i} \delta(\omega - \omega_i)}$$

$$\bullet \langle \hat{x}(t) \hat{x}(t') \rangle = \frac{\hbar}{\pi} \int_0^{\omega_c} d\omega J(\omega) \left[\coth\left(\frac{\hbar \omega}{2k_B T}\right) \cos \omega (t-t') - i \sin \omega (t-t') \right]$$

And calculating it we got this particular expression which further can be expressed in a little bit simpler form defining the as usual the bath spectral density. Using bath spectral density we have written down the autocorrelation function auto correlator here.

(Refer Slide Time: 04:35)

$$J(\omega) = m \gamma_m \omega$$

$$\bullet \boxed{\langle \hat{x}(t) \hat{x}(t') \rangle = \frac{m \gamma_m \omega_c}{\pi} \int_0^{\omega_c} d\omega \hbar \omega \left[\coth\left(\frac{\hbar \omega}{2k_B T}\right) \cos \omega (t-t') - i \sin \omega (t-t') \right]}$$

In the classical limit: $\hbar \rightarrow 0$
 $\coth\left(\frac{\hbar \omega}{2k_B T}\right) \approx \frac{2k_B T}{\hbar \omega}$

$\omega_c \rightarrow \infty$

$$\boxed{\langle \hat{x}(t) \hat{x}(t') \rangle = 2m \gamma_m k_B T \delta(t-t')}$$

And in considering the Ohmic damping, we got the expression for the autocorrelation for the Langevin noise which is also known as the second moment of the Langevin noise and as usual in the classical limit, it gives it should give the classical expression which we obtained. We see that this autocorrelator depends only on the time difference.

(Refer Slide Time: 05:08)

$$\langle \hat{x}(t) \hat{x}(t') \rangle = 2m\gamma_m k_B T \delta(t-t')$$

$$\langle \hat{x}(t) \hat{x}(t') \rangle = m\hbar\gamma_m \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{-i\omega(t-t')} \omega \left[\coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1 \right]$$

$(\tau = t-t')$

$$\langle \hat{x}(\tau) \hat{x}(0) \rangle = m\hbar\gamma_m \int_{-\infty}^{\infty} \frac{d\omega}{2\pi} e^{-i\omega\tau} \omega \left[\coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1 \right]$$

So defining a parameter tau which is the time difference of this which basically denotes the time difference. So using this parameter tau, we write down the autocorrelation function in this particular form. After that, we calculated the quantum spectral noise density. And to do that, we just have to work out the Fourier transform of the correlator.

(Refer Slide Time: 05:36)

Quantum spectral noise density

$$S_{\hat{x}\hat{x}}(\omega) = m\hbar\gamma_m \left[\omega \coth\left(\frac{\hbar\omega}{2k_B T}\right) + 1 \right]$$

$$S_{\hat{x}\hat{x}}(\omega) = 2m\hbar\gamma_m \omega (n(\omega) + 1) \quad ; \quad \omega > 0$$

And doing that we get the expression for the spectral, quantum spectral noise density for omega greater than zero and we have worked it out for omega less than zero also.

(Refer Slide Time: 05:46)

$$S_{\xi\xi}(\omega) = 2m\hbar\tau_m\omega (n(\omega) + 1) \quad ; \quad \omega > 0$$

$$S_{\xi\xi}(-\omega) = \int_{-\infty}^{\infty} d\tau \langle \xi(\tau)\xi(0) \rangle e^{-i\omega\tau} \quad ; \quad \omega < 0$$

$$S_{\xi\xi}(-\omega) = 2m\hbar\tau_m\omega n(\omega)$$

So we worked out the quantum spectral noise density at plus omega and at minus omega.

(Refer Slide Time: 05:56)

$$S_{\xi\xi}(-\omega) = 2m\hbar\tau_m\omega n(\omega)$$

$$S_{\xi\xi}(\omega) \neq S_{\xi\xi}(-\omega) \quad \underline{\text{Not symmetric}}$$

And it turns out that this function is not symmetric which is unlike the classical case. In the classical case, we saw that this noise, spectral noise density is a symmetric function.

(Refer Slide Time: 06:10)

In the classical limit: $\hbar \rightarrow 0$
 $k_B T \gg \hbar \omega$,
 $n(\omega) \approx \frac{k_B T}{\hbar \omega}$

$$\begin{cases} S_{\hat{x}\hat{x}}(\omega) = 2m\gamma_m k_B T \\ S_{\hat{x}\hat{x}}(-\omega) = 2m\gamma_m k_B T \end{cases}$$

If temp is high, but $\hbar \neq 0$
 we can write approximately:

$$2m\gamma_m \hbar \omega [n(\omega_m) + 1]$$

In the classical limit obviously, again we obtain the classical expression for the spectral noise density.

(Refer Slide Time: 06:22)

Quantum Noise Effects on an optical mode

$$H = \hbar \omega_0 \hat{a}^\dagger \hat{a} + \sum_i \hbar \omega_i \hat{b}_i^\dagger \hat{b}_i + i\hbar \left(\Omega_{drive} \hat{a}^\dagger e^{-i\omega t} + \Omega_{drive} \hat{a} e^{i\omega t} \right) + \sum_i \hbar \left(\Omega_i \hat{a} \hat{b}_i^- + \Omega_i \hat{a}^\dagger \hat{b}_i^+ \right)$$

^
9
/
10
v

Finally, we started discussing the quantum noise effect on an optical mode in the context of a Fabry-Perot cavity, because the Fabry-Perot cavity is at the backbone of any cavity optomechanical system. Here we considered one of the mirror in the Fabry-Perot cavity to be perfectly reflecting and the other mirror to be partially transmissive. And vacuum fluctuation enters into the cavity from one side.

And if it is a cavity optomechanical system then it is usually always drive by a single mode laser having frequency ω_L .

(Refer Slide Time: 07:02)

vacuum \hat{a}_{in} \hat{a} Fabry-Pérot cavity

$$H = \hbar\omega_0 \hat{a}^\dagger \hat{a} + \sum_c \hbar\omega_c \hat{b}_i^\dagger \hat{b}_i + i\hbar \left(\Omega_{drive} \hat{a} e^{-i\omega t} - \Omega_{drive}^\dagger \hat{a}^\dagger e^{i\omega t} \right) + \sum_c \hbar \left(\Omega_i \hat{a} \hat{b}_i^\dagger + \Omega_i^\dagger \hat{a}^\dagger \hat{b}_i \right)$$

$[\hat{b}_i, \hat{b}_j^\dagger] = \delta_{ij}$

We wrote down the quantum mechanical Hamiltonian for a system N bath. Here the first term refers to the energy of the cavity mode. The second term describes the energy of the bath oscillator modelled as a collection of independent electromagnetic oscillators with the constraint that this commutation relation has to be obeyed.

That is the commutation between say b_i, b_j^\dagger should be equal to δ_{ij} . And the third term describe the laser driving the cavity externally. The fourth and the final term, this is the final term. It refers to the system bath coupling. The strength of the coupling between the cavity mode and the bath operator is given by the parameter ω_i . This Hamiltonian is the basis of our analysis for the rest of this lecture.

Now let us go over to the continuum limit because ultimately this bath oscillators are infinite in numbers.

(Refer Slide Time: 08:14)

$$\sum_i \longrightarrow \frac{1}{\Delta\omega} \int d\omega$$

$$\Delta\omega \rightarrow 0$$

$$b_i \longrightarrow (\Delta\omega)^{1/2} b(\omega)$$

$$b_i^\dagger \longrightarrow (\Delta\omega)^{1/2} b^\dagger(\omega)$$

$$\int \delta(\omega - \omega') d\omega = 1$$

So when we go over to the continuum limit, this summation sign is going to be replaced by integral. In fact, this summation is over the discrete index i and it turns into an integration over the bath oscillator frequency ω . And it has to be dimensionless. So it is divided by say $\Delta\omega$ here. $\Delta\omega$ is the mode spacing and we take it in the limit say $\Delta\omega$ tends to 0.

And the bath operators undergoes this kind of transformation. So I had explained it. So we have say b_i the discrete variable. Now in the continuum limit, it will become $\Delta\omega^{1/2} b(\omega)$ and b_i^\dagger in the discrete space it is going to be $\Delta\omega^{1/2} b^\dagger(\omega)$ in the continuum.

Also please note that in continuum we have this relation $\int \delta(\omega - \omega') d\omega = 1$.

(Refer Slide Time: 09:39)

$$\int \delta(\omega - \omega') d\omega = 1$$

$$\delta_{ij} \longrightarrow \delta(\omega - \omega') \Delta\omega$$

$$[b_i, b_j^\dagger] = \delta_{ij}$$

$$\longrightarrow [b(\omega), b^\dagger(\omega')] = \delta(\omega - \omega')$$

On the other hand you know that in the discrete space we have this Kronecker delta. Now in the continuum it will be replaced by delta omega minus omega dash delta omega. So therefore, this commutation relation in the discrete space $b_i b_j^\dagger$ is equal to delta ij. In the continuum limit it would be replaced by $b(\omega) b^\dagger(\omega')$ is equal to delta omega minus omega dash.

So these are very important relations. So utilizing all these now we can rewrite this Hamiltonian. This Hamiltonian is in the discrete space. Now in the continuum space, this Hamiltonian can be written as follows.

(Refer Slide Time: 10:33)

$$\hat{H} = \hbar\omega_0 \hat{a}^\dagger \hat{a} + \int d\omega \hbar\omega b(\omega) b^\dagger(\omega) + i\hbar \left(\frac{\Omega_{drive}}{2} \hat{a}^\dagger e^{-i\omega_L t} - \frac{\Omega_{drive}^*}{2} \hat{a} e^{i\omega_L t} \right) + \hbar \int d\omega \left[\frac{\Omega^*(\omega)}{2} \hat{a}^\dagger b(\omega) + \frac{\Omega(\omega)}{2} \hat{a} b^\dagger(\omega) \right]$$

$$[a, a^\dagger] = 1$$

$$\dot{\hat{a}} = \frac{1}{i\hbar} [\hat{a}, \hat{H}]$$

$$= -i\omega_0 \hat{a} + \frac{\Omega_{drive}}{2} e^{-i\omega_L t}$$

So we will write this Hamiltonian as $\hbar\omega_0 \hat{a}^\dagger \hat{a}$. So both oscillators are now going from the discrete to the continuum. So we have now integration d

$\omega \hbar \times \omega$. Let me just show you. So this summation is now replaced by integral. So $d\omega \hbar \times \omega b^\dagger \omega$ and b of ω . And this external laser drive would remain same because it just involve the optical mode only.

It does not involve the bath oscillator, so it will remain as it is. So you will have a $\dagger e$ to the power $\omega L t$ minus ω drive the complex conjugate a e to the power $i \omega L t$. And finally the bath and the mode coupling that would be again this bath oscillators are involved.

So it would be replaced by integral $\hbar \times$ integration $d\omega$, ω star ω a $b^\dagger \omega$ plus ω , this capital ω ω and we have a $\dagger b$ of ω . So this is going to be the key Hamiltonian now. And we can immediately write couple of things from here. First of all, we can calculate the Heisenberg equation or motion for the mode operator.

So that would be a dot is equal to time derivative of the mode operator would be 1 by $i \hbar \times$ the commutation between a and H . So you can already we have done this kind of stuff too many times in the course. So immediately you can write, it will be ω a plus ω drive e to the power $\omega L t$. You can verify it because commutation with a and $a^\dagger a$ will give you simply a .

And then this bath oscillators are independent of the mode cavity mode. So therefore, this term is not going to contribute. And then you have this particular term. From this term you are having this term and what else you will be left is the last term because a and a^\dagger is there. So a, a^\dagger is equal to 1 . So we have to exploit a, a^\dagger is equal to 1 . So exploiting that you will have this particular term now.

(Refer Slide Time: 13:25)

$$\hat{a} = \frac{1}{i\hbar} [\hat{a}, H]$$

$$\Rightarrow \hat{a} = -i\omega_0 \hat{a} + \Omega_{drive} e^{-i\omega_0 t} - i \int d\omega \Omega(\omega) \hat{b}(\omega)$$

$$\dot{\hat{b}} = \frac{1}{i\hbar} [\hat{b}, H]$$

That would be minus i integration d omega capital omega of omega b of omega. So this is for the optical mode, time derivative of the optical mode operator. Similarly, for the bath mode we can calculate. That would be time derivative of b. That is 1 by ih cross b of H.

(Refer Slide Time: 13:55)

$$\dot{\hat{b}} = \frac{1}{i\hbar} [\hat{b}, H]$$

$$= \frac{1}{i\hbar} \left[\int d\omega' \hbar\omega' [\hat{b}(\omega), \hat{b}^\dagger(\omega') \hat{b}(\omega')] + \hbar \int d\omega' \Omega^*(\omega') \hat{a} [\hat{b}(\omega), \hat{b}^\dagger(\omega')] \right]$$

$$= -i \left[\int d\omega' \omega' \delta(\omega - \omega') \hat{b}(\omega') \right]$$

So here let me show you the calculation. This is also easy. 1 by i h cross. Now I have integration because a dagger a, this part is not going to contribute because these are independent as I said. So we will have, from the next term we will have say this is d omega dash h cross omega dash b of omega and here I have b dagger of omega dash b of omega dash, okay. Let me show it here.

So I am now talking about this particular term, okay. And then we have \hbar cross d ω dash ω star of ω dash a . And we have b of ω b dagger of ω dash. So this is what we will have now. And you can, okay let us evaluate it. You will have minus i say integration $d\omega$ dash ω dash. And we now use the commutation relation between this relation we are going to use, this one we are going to use.

If we use it then you will have here $\delta(\omega - \omega')$ $b(\omega')$ of ω dash.

(Refer Slide Time: 15:27)

$$\begin{aligned}
 & + \hbar \int d\omega' \Omega^*(\omega') a [b(\omega), b^\dagger(\omega')] \\
 & = -i \left[\int d\omega' \omega' \delta(\omega - \omega') b(\omega') \right. \\
 & \quad \left. + \int d\omega' \Omega^*(\omega') a \delta(\omega - \omega') \right] \\
 \Rightarrow \quad \dot{\hat{b}} & = -i\omega b(\omega) - i\Omega^*(\omega) a
 \end{aligned}$$

And then next term would be $d\omega$ dash ω star of ω dash a $\delta(\omega - \omega')$ $b(\omega')$ minus ω dash. Then we can utilize the property of the Dirac delta function and this will give us the equation of motion for the bath or the mode and that would be b dagger b dot is equal to minus i ω b of ω minus i Ω star of ω into a . So this is the equation we get. We can write a formal solution to this part equation.

(Refer Slide Time: 16:05)

Take, $b = \tilde{b} e^{-i\omega t}$

$$\dot{b} = \dot{\tilde{b}} e^{-i\omega t} - i\omega \tilde{b} e^{-i\omega t}$$

$$\dot{\tilde{b}} e^{-i\omega t} - i\omega \tilde{b} e^{-i\omega t} = -i\omega \tilde{b} e^{-i\omega t} - i\Omega^*(\omega) a$$

$$\Rightarrow \boxed{\dot{\tilde{b}} = -i\Omega^*(\omega) a e^{i\omega t}}$$

To do that, let us make a change of variables. Let me take b is equal to \tilde{b} e to the power minus i ω t . Then I will have \dot{b} is equal to $\dot{\tilde{b}}$. I am taking the time derivative e to the power minus i ω t minus i ω \tilde{b} e to the power minus i ω t . Then if I put it here in this equation, then I will get it as $\dot{\tilde{b}}$ e to the power minus i ω t minus i ω \tilde{b} e to the power minus i ω t .

And on the right hand side I have minus i ω \tilde{b} e to the power minus i ω t minus i ω Ω^* ω a . Now as you can see from this equation that this particular term and this term get cancelled out and we will have from here we will have $\dot{\tilde{b}}$ is equal to minus i Ω^* of ω a e to the power i ω t , okay. So now integrating both sides from some initial time t_0 .

(Refer Slide Time: 17:40)

$$\int_{t_0}^t \dot{\tilde{b}} dt' = -i\Omega^* \int_{t_0}^t a(t') e^{i\omega t'} dt'$$

$$\Rightarrow \tilde{b}(\omega, t) - \tilde{b}(\omega, t_0) = -i\Omega^* \int_{t_0}^t a(t') e^{i\omega t'} dt'$$

$$\Rightarrow \boxed{b(\omega, t) = b(\omega, t_0) e^{-i\omega(t-t_0)} - i\Omega^*(\omega) \int_{t_0}^t a(t') e^{-i\omega(t-t')} dt'}$$

So let me integrate it on both sides from some say initial time t_0 to some time t and accordingly here also I have minus ω^* t_0 to t $a(t')$ $e^{i\omega t'}$ dt' . So if I do the integration, this is going to give me $\tilde{b}(\omega, t)$ minus $\tilde{b}(\omega, t_0)$. That would be equal to minus $i\omega^*$. This will remain the same.

It would be t_0 to t $a(t')$ $e^{i\omega t'}$ dt' . And from here I can now rewrite actually this in the variable b of ω, t . So b of ω, t is equal to b of ω, t_0 $e^{-i\omega(t-t_0)}$ minus $i\omega^*$ $\int_{t_0}^t a(t') e^{-i\omega(t-t')} dt'$ okay. So this is what we get as our formal solution.

(Refer Slide Time: 19:24)

$$\Rightarrow \tilde{b}(\omega, t) - \tilde{b}(\omega, t_0) = -i\omega^* \int_{t_0}^t a(t') e^{i\omega t'} dt'$$

$$\Rightarrow b(\omega, t) = b(\omega, t_0) e^{-i\omega(t-t_0)} - i\omega^*(\omega) \int_{t_0}^t a(t') e^{-i\omega(t-t')} dt'$$

free evolution of the bath

represents waves radiated by the cavity into the bath

In fact, you see here the first term on the right hand side this particular term, this term corresponds to the free evolution of the bath while the second term here it represents waves radiated by the cavity into bath. So this particular term, this second term represents, it represents waves, waves radiated by the cavity into the bath.

And on the other hand this particular term represents as I said it is free evolution of the bath, okay. Now we can substitute this particular solution, this bath solution into the equation for the optical mode here. So we can put b of ω into this equation. So then what we will obtain this. Let me write that here. Okay let me first bring the solution to the address or let me first write it then I will put it.

(Refer Slide Time: 20:50)

$$\dot{a} = -i\omega_0 a + \Omega_{\text{drive}} e^{-i\omega_L t} - i \int d\omega \Omega(\omega) b(\omega, t_0) e^{-i\omega(t-t_0)} - \int d\omega \frac{|\Omega(\omega)|^2}{\omega} \int_{t_0}^t a(t') e^{-i\omega(t-t')} dt'$$

So I have to put my bath solution in this equation a dot is equal to minus i omega not a plus omega drive e to the power minus i omega L t. And I have here minus i integration d omega, omega here. And then this whole thing I have to put. So because I have two terms I will get two terms. So let me just write it one by one. The first term I will have is this.

I will have b of omega t 0 e to the power minus i omega t minus t 0. And the second one is going to give me d omega mod of capital omega of omega whole square integration t 0 to t a of t dash e to the power minus i omega t minus t dash dt dash. This is coming because you see that this complex conjugate is there here and okay. So because of that and in the, here we have this omega, okay.

And because in the second term we have that complex conjugate that is why this mod of capital omega, omega square term is coming.

(Refer Slide Time: 22:29)

→ Assume that the coupling Ω is constant for all bath frequencies ω

$$|\Omega(\omega)|^2 = \frac{\kappa}{2\pi}, \quad \kappa \text{ is related to the cavity bandwidth}$$

$$\delta\nu = \frac{\omega_+ - \omega_-}{2\pi} = \frac{\kappa}{2}$$

Now assume, let us assume that which we will justify it later for this particular identification that we are going to make now. Assume that the coupling, the coupling Ω , Ω is the coupling between the bath and the optical mode. The coupling Ω is constant for all frequencies, for all bath frequencies ω .

And let us write it as this Ω^2 is equal to κ by 2π where κ is related to the cavity bandwidth. κ is related to the cavity bandwidth. So I mean to say the bandwidth would be something like this. $\delta\nu$ is equal to say $\omega_+ - \omega_-$ divided by 2π and $\omega_+ - \omega_-$ is equal to κ .

That is the width is say κ divided by 2π . So this is what we have. Now with this, we can write the equation for the optical mode as follows.

(Refer Slide Time: 24:04)

$$\dot{a}(t) = -i\omega_0 a + \Omega_{\text{drive}} e^{-i\omega_L t} - i \sqrt{\frac{\kappa}{2\pi}} \int_{-\infty}^{\infty} d\omega b(\omega, t_0) e^{-i\omega(t-t_0)}$$

$$- \frac{\kappa}{2\pi} \int_{t_0}^t dt' a(t') \int_{-\infty}^{\infty} d\omega e^{-i\omega(t-t')}$$

$2\pi \delta(t-t')$

So we will have a dot t is equal to minus i omega 0 a plus omega drive e to the power minus i omega L t minus i square root of kappa by 2 pi integration minus infinity to plus infinity d omega b of omega, okay. So b of omega at t 0 e to the power minus i omega t minus t 0 minus kappa by 2 pi. I am basically replacing omega by square root of kappa by 2 pi and mod omega square capital omega square is equal to kappa by 2 pi.

So I am rewriting it only, nothing new I am doing here, t 0 to t dt dash a of t dash integration minus infinity to plus infinity d omega e to the power minus i omega t minus t dash. Now you may recognize that this particular term is nothing but the Dirac delta function. So it is 2 pi into, this is the delta function, delta t minus t dash. So let us look at this particular term this last term, this last term let us look at specifically.

(Refer Slide Time: 25:48)

$$\frac{\kappa}{2\pi} \int_{t_0}^t dt' a(t') 2\pi \delta(t-t')$$

Set $t_0 \rightarrow 0$ and $t \rightarrow \infty$

$$\kappa \int_0^\infty dt' a(t') \delta(t-t')$$

We have kappa by 2 pi integration t 0 to t dt dash a of t dash, and here I have 2 pi delta t minus t dash. Then setting t 0, this setting t 0 at 0 and this upper limit t at infinity, we will have it as kappa 0 to infinity dt dash a of t dash delta t minus t dash.

(Refer Slide Time: 26:38)

$$\frac{\kappa}{2} \int_{-\infty}^{\infty} dt' a(t') \delta(t-t') = \frac{\kappa}{2} a$$

$$a_{in} = \frac{i}{\sqrt{2\pi}} \int_{-\infty}^{\infty} d\omega b(\omega, t_0) e^{-i\omega(t-t_0)}$$

$$\dot{a}(t) = -i\omega_0 a + \Omega_{drive} e^{-i\omega_L t} - \frac{\kappa}{2} a - \sqrt{\kappa} a_{in}$$

But without loss of generality, rather than setting t 0 at 0, we can set it as minus infinity and then we will have it as, because we are setting at minus infinity we have to divide it by half. And then we will have dt dash a of t dash delta t minus t dash. This will give me, now applying the property of the Dirac delta function I will have it as kappa by 2 a. So in the again the last term as you see it is get simplified significantly.

We are having only this $\kappa/2$ from the last term. On the other hand in this third term, if we define a parameter say defined as this say a_{in} is equal to i divided by square root of 2π integration minus infinity to plus infinity $d\omega$ b of ω t_0 e to the power minus $i\omega t - t_0$, okay. Then we can rewrite this equation for, time evolution equation for the optical mode in a very simplified form.

And that would be \dot{a} is equal to minus $i\omega_0 a$ plus $\omega_{drive} e$ to the power minus $i\omega L t$. Now the last term the fourth term here that is $\kappa/2$ let me put it first here, minus $\kappa/2 a$. And the third term we will have here root over κa_{in} . So this is a very important equation that now we have obtained.

(Refer Slide Time: 28:33)

$$- \sqrt{\kappa} a_{in}$$

- damping of the optical mode occurs at rate $\frac{\kappa}{2}$

$\sqrt{\kappa} a_{in} \rightarrow$ Langevin noise operator

- $\langle a_{in} \rangle = 0$
- $\langle a_{in}(t) a_{in}(t') \rangle = \delta(t-t')$

Clearly from this equation as you can see that the damping of the optical mode damping of the optical mode occurs at the rate $\kappa/2$ or in other words the corresponding energy loss occurs at the rate κ and which is expected behavior of cavity oscillator and this is one of the reason why we have identified this particular term as this, alright.

And this particular term the last term now here, this term is very important. And you can recognize that this is nothing but the Langevin noise operator. This is Langevin noise operator. This is Langevin noise operator. Since a_{in} has a vanishing mean value, we can show that it has a vanishing mean value and the autocorrelation is a delta function. So autocorrelation a_{in} of t and a_{in} of t' would turn out to be delta function.

So and you know that this is these are the properties of quantum Langevin noise also. And then hence we can identify this last term as the nothing but the Langevin noise. So let us actually prove it.

(Refer Slide Time: 30:10)

$$\sqrt{\kappa} a_{in} \rightarrow \text{Langevin noise operator}$$

$$=$$

- $\langle a_{in} \rangle = 0$
- $\langle a_{in}^\dagger(t) a_{in}(t') \rangle = \bar{n}(\omega_0) \delta(t-t')$

$$\rightarrow \langle a_{in} \rangle = \frac{i}{\sqrt{2\pi}} \int_{-\infty}^{\infty} d\omega \langle b(\omega, t_0) \rangle e^{-i\omega(t-t_0)}$$

$$= 0$$

If we assume that the bath is a thermal state, then we can write the expectation value of a_{in} is equal to i by square root of 2π integration minus infinity to plus infinity $d\omega$ the expectation value of this annihilation operator with e to the power minus $i\omega(t-t_0)$. Now it is very clear and it is actually obvious that since the annihilation and creation operator have no diagonal elements, so this is going to give us simply 0. So this expectation value of this Langevin noise is 0 here.

(Refer Slide Time: 31:02)

$$= 0$$

$$\langle a_{in}^\dagger(t) a_{in}(t') \rangle$$

$$= \left\langle \frac{1}{2\pi} \int_{-\infty}^{\infty} d\omega b^\dagger(\omega, t_0) e^{i\omega(t-t_0)} \int_{-\infty}^{\infty} d\omega' b(\omega', t_0) e^{-i\omega'(t-t_0)} \right\rangle$$

We can now calculate the autocorrelation. To do that let us work out. a in dagger t in a at some different times say t dash. Let us first calculate it. Let us put the expression of a in from here. So if we put it here, I have 1 by 2π . So there are two a in. So square root of 2π is there from one term and for another square root of 2π . And in one case we are taking a in dagger.

So it will be minus i . So minus i into i will give us plus 1 . So therefore, it will be 1 by 2π . And we will have integration minus infinity to plus infinity d of d omega b dagger omega t_0 e to the power i omega t minus t_0 . And from the other a in I have to take the expectation value.

So from the other one I have minus infinity to plus infinity d omega dash b omega dash t_0 e to the power minus i omega dash t minus t_0 . So let me close the bracket.

(Refer Slide Time: 32:42)

$$\begin{aligned}
 &= \frac{1}{2\pi} \int_{-\infty}^{\infty} d\omega \int_{-\infty}^{\infty} d\omega' \langle \underbrace{b^\dagger(\omega, t_0) b(\omega', t_0)}_{\substack{e^{i\omega(t-t_0)} e^{-i\omega'(t-t_0)}}} \rangle \\
 &\quad \downarrow \\
 &\quad \underline{\underline{\bar{n}(\omega')}} \delta(\omega - \omega') \\
 &= \frac{\bar{n}(\omega_0)}{2\pi} \int_{-\infty}^{\infty} d\omega e^{i\omega(t-t')}
 \end{aligned}$$

And then I have 1 by 2π integration minus infinity to plus infinity d omega integration minus infinity to plus infinity d omega dash expectation value of b dagger omega t_0 b of omega dash t_0 and I have e to the power i omega t minus t_0 . And here I have e to the power minus i omega dash t minus t_0 . Now you see this particular term this is the expectation value of the number operator for phonons.

So this is going to give us, it would become phonon number n of omega, let us say n of omega dash. And then this would be delta function, delta omega minus omega

dash. So using this we can immediately write here as \bar{n} of average number of phonons assuming that the bath occupation number peaks at this cavity frequency ω_0 .

So then I can take this out and I have \bar{n} ω_0 zero divided by 2π integration minus infinity to plus infinity $B \omega_0 e^{i \omega_0 t - t'}$. And you know this is nothing but the delta function so along with $1/2\pi$.

(Refer Slide Time: 34:33)

$$= \bar{n}(\omega_0) \delta(t-t')$$

Sly,

$$\langle a_{in}(t) a_{in}^\dagger(t') \rangle = [\bar{n}(\omega_0) + 1] \delta(t-t')$$

So this would be \bar{n} of ω_0 delta $t - t'$. So in fact, what I should have written here earlier as I said we are now going to prove it. So let me write here it is a dagger here and here let me put \bar{n} of ω_0 . So this is the correct one. So as you see the autocorrelation function is a delta function. Similarly, you can show that, now here we have worked out a dagger a_{in} .

We can show the other one also that is $a_{in} a_{in}^\dagger$ at some different time $t - t'$. This autocorrelation function in the similar way you can work out and you can show that this would be \bar{n} of ω_0 assuming that again that the bath occupation number peaks at this cavity frequency. Then you will have this particular expression delta $t - t'$, okay.

Now one thing has to be kept in mind that this is a thermal oscillation, thermal oscillator. So generally these are in microwave frequency and so on.

(Refer Slide Time: 36:01)

$$= [\bar{n}(\omega_0) + 1] \delta(t - t')$$

At optical frequencies: $\omega_0 \sim 10^{15} \text{ Hz}$
 $T \sim 300 \text{ K}$

$$\frac{\hbar\omega_0}{k_B T} \ll 1 \Rightarrow \bar{n}(\omega_0) \sim 0$$

$$\langle a_{in}^\dagger(t) a_{in}(t') \rangle = 0$$

$$\langle a_{in}(t) a_{in}^\dagger(t') \rangle = \delta(t - t')$$

But at optical frequency if I talk about at, optical frequencies where ω_0 is on the order of 10 to the power 15 hertz, and if we will consider room temperature that is around 300 Kelvin, in that case this $\hbar \omega_0$ by $k_B T$ is much less than 1 . That means $k_B T$ is much higher than $\hbar \omega_0$. And this implies that this phonon number or optical photons, that would be, average number would be nearly 0 .

And in that case at optical frequencies we will have $\langle a_{in}^\dagger(t) a_{in}(t') \rangle$ this autocorrelation will give us 0 . On the other hand, the other one $\langle a_{in}(t) a_{in}^\dagger(t') \rangle$ that would be this delta function, $\delta(t - t')$, okay. This we have done for the, in the time domain.

(Refer Slide Time: 37:19)

$$\begin{aligned} & \langle a_{in}(\omega) a_{in}^\dagger(\omega') \rangle \\ &= \left\langle \int_{-\infty}^{\infty} dt a_{in}(t) e^{i\omega t} \int_{-\infty}^{\infty} dt' a_{in}^\dagger(t') e^{i\omega' t'} \right\rangle \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dt dt' \end{aligned}$$

So we can work out in the frequency domain as well this correlation in the frequency domain and that is very straightforward to calculate. So I mean to say let us calculate $a_{in}(\omega)$ and $a_{in}(\omega')$ say ω' . So this is in the frequency domain. So you can calculate. First let me do it, let me write the Fourier transform of it that is minus infinity to plus infinity dt $a_{in}(t) e^{i\omega t}$.

And here it is minus infinity to plus infinity for the second term, for this term. I have here say dt' $a_{in}(t')$ $e^{i\omega' t'}$. Let me close the bracket. Then I have minus infinity to plus infinity, minus infinity to plus infinity $dt dt'$. The expectation value of $a_{in}(t) a_{in}(t')$. And I have here $e^{i(\omega t + \omega' t')}$ to the power $i(\omega t + \omega' t')$.

(Refer Slide Time: 38:48)

$$\begin{aligned}
 &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dt dt' \langle a_{in}(t) a_{in}^{\dagger}(t') \rangle e^{i(\omega t + \omega' t')} \\
 &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} dt dt' \delta(t-t') e^{i[\omega t' + \omega(\tau+t')]} \\
 &= \int_{-\infty}^{\infty} dt' e^{i(\omega + \omega')t'} \int_{-\infty}^{\infty} d\tau \delta(\tau) e^{i\omega\tau}
 \end{aligned}$$

$$\Rightarrow \langle a_{in}(\omega) a_{in}^{\dagger}(\omega') \rangle = 2\pi \delta(\omega + \omega')$$

Now I know the result for this one and utilizing that minus infinity to plus infinity, minus infinity to plus infinity $dt dt'$. And this guy gives me $\delta(t - t')$ this one and I have $e^{i(\omega t + \omega' t')}$. Actually I can write it, all right let me do it $i(\omega t + \omega' t')$ is I can consider it as τ . Then I will have here $e^{i(\omega + \omega')t'}$ and $t - t'$ if I replace t by $\tau + t'$ then I will have a term $\omega\tau + \omega t'$, okay.

So this is what I will have. And using this one I can then next I can write minus infinity to plus infinity $dt dt'$ $e^{i(\omega + \omega')t'}$ integration minus infinity to plus infinity $d\tau \delta(\tau) e^{i\omega\tau}$, okay. And then this is the delta function, so apply the property of the delta function.

So we will get from here, very simply we will have a in omega a in dagger of omega dash.

That would be equal to 2 pi. And this is going to give us 1, okay. So I will have this is the Dirac delta function again. That would be 2 pi delta into delta of omega plus omega dash.

(Refer Slide Time: 40:42)

$$b(\omega, t) = b(\omega, t_0) e^{-i\omega(t-t_0)} - i\Omega^*(\omega) \int_{t_0}^t dt' a(t') e^{-i\omega(t-t')}$$

$$b(\omega, t) = b(\omega, t_1) e^{-i\omega(t-t_1)} + i\Omega^*(\omega) \int_t^{t_1} dt' a(t') e^{-i\omega(t-t')}$$

Now in contrast to the bath mode solution, we can write another solution in terms of a final time t_1 , rather than the initial time t_0 . While we have written this particular solution, we went from the initial time t_0 to some given time t , some instant of time t . We can have another solution where we can go from the say final time t_1 to this time t . That means we are now we can go in the backward direction in time.

If we do that, then we will get a solution of this type. That would be b of omega t . That would be equal to b of omega t_1 , e to the power minus i omega t minus t_1 . Here instead of this minus sign, and that is going to matter a lot, we will get a plus i omega star of omega integration from t to t_1 dt dash a of t dash e to the power minus i omega t minus t dash. This can be worked out very easily. Let me just quickly show you how to do that.

(Refer Slide Time: 42:13)

$$\dot{\tilde{b}} = -i\Omega^* a e^{i\omega t}$$

Integrating both sides from t_1 to t

$$\tilde{b}(\omega, t) - \tilde{b}(\omega, t_1) = -i\Omega^* \int_{t_1}^t dt' a(t') e^{i\omega t'}$$

$$\Rightarrow b(\omega, t) e^{i\omega t} - b(\omega, t_1) e^{i\omega t_1} = i\Omega^* \int_{t_1}^t dt' a(t') e^{i\omega t'}$$

We can again begin from the change of variable for the bath and if we take the change of variable that is we introduced this quantity \tilde{b} . So $\dot{\tilde{b}}$ is equal to minus $i\Omega^* a e^{i\omega t}$. Let me quickly take you back to the way we have done it earlier. So while we have done it, as you see. Yes, this is where our original bath mode equation, time evolution equation for the bath mode.

Then going over to this new variable \tilde{b} , we got rid of this particular term and we have then this particular equation. So here also in the similar way, I am starting with this particular equation. So integrating both sides, integrating both sides from this final time t_1 to some time t we can immediately write $\tilde{b}(\omega, t) - \tilde{b}(\omega, t_1)$. That will be equal to minus $i\Omega^* \int_{t_1}^t dt' a(t') e^{i\omega t'}$.

This I can now write as going back to the original variable that is $b(\omega, t) e^{i\omega t} - b(\omega, t_1) e^{i\omega t_1}$ and this is equal to, now let me just reverse the integration. So here I now go from t to t_1 . So I will have a plus $i\Omega^* \int_t^{t_1} dt' a(t') e^{i\omega t'}$, okay.

(Refer Slide Time: 44:34)

$$\Rightarrow b(\omega, t) = b(\omega, t_1) e^{-i\omega(t-t_1)} + i\Omega^*(\omega) \int_{t_1}^t dt' a(t') e^{-i\omega(t-t')}$$

$$\dot{a} = -i\omega_0 a + \Omega_{\text{drive}} e^{-i\omega_L t} - i \int d\omega \Omega(\omega) b(\omega, t)$$

So from here I get b of ω at t is equal to b of ω at t_1 e to the power minus i ω t minus t_1 plus i Ω^* of ω integration t to t_1 dt' a of t' e to the power minus i ω t minus t' . Now we can put this solution into the equation for the cavity mode, the equation that we obtained.

That is \dot{a} is equal to minus i $\omega_0 a$ plus $\Omega_{\text{drive}} e$ to the power minus i $\omega_L t$ minus i integration $d\omega$ capital Ω of ω b of ω t . So let me put it here, this particular solution if I put it here.

(Refer Slide Time: 45:45)

$$\dot{a} = -i\omega_0 a + \Omega_{\text{drive}} e^{-i\omega_L t} + \frac{\kappa}{2} a - \sqrt{\kappa} a_{\text{out}}$$

$$a_{\text{out}} = \frac{i}{\sqrt{2\pi}} \int_{-\infty}^{\infty} d\omega b(\omega, t_1) e^{-i\omega(t-t_1)}$$

↑
represents waves travelling out from the cavity into the bath

And in the similar fashion, we will be able to get the equation, time evolution equation for the optical mode in this form and when we go into the backward direction in time now I have \dot{a} is equal to minus i $\omega_0 a$ plus $\Omega_{\text{drive}} e$ to

the power minus $i\omega L t$ plus now here we have plus κ by 2 a and minus root over κ . Here I will define a new variable a_{out} .

Earlier we had a_{in} . So here I am defining a variable a_{out} which is defined as a_{out} is equal to, this is also Langevin noise. It is i by square root of 2π integration minus infinity to plus infinity $d\omega$ b of ω t 1 e to the power minus $i\omega t$ minus t 1 . This one actually represents, this represents waves traveling out from the cavity, traveling out from the cavity into the bath.

And intuitively you can see that this is this makes really sense because now we are going in the final time to the some instant of time t .

(Refer Slide Time: 47:26)

$$\dot{a} = -i\omega_0 a + \Omega_{drive} e^{-i\omega_L t} + \frac{\kappa}{2} a - \sqrt{\kappa} a_{out} \rightarrow (ii)$$

↓

$$-\kappa a - \sqrt{\kappa} a_{in} + \sqrt{\kappa} a_{out} = 0$$

⇒ $a_{out} = a_{in} + \sqrt{\kappa} a$

So therefore, we get two equations for the bath optical mode, when we go in the forward direction in time and that equation that we got is this. It is a dot is equal to minus $i\omega_0 a$ plus $\Omega_{drive} e$ to the power minus $i\omega L t$ minus κ by 2 a minus square root of κ a_{in} and let me say this is my equation 1. And another equation I got when I go in the backward in the time direction.

That is minus $i\omega_0 a$ plus $\Omega_{drive} e$ to the power minus $i\omega L t$. And I will have here plus κ by 2 a minus square root of κ a_{out} . So let me term it as equation number 2. Now if we subtract equation 2 from equation 1 then we will obtain this minus κa is minus square root of κ , you can easily see this, a_{in} plus square root of κ a_{out} , that is equal to 0.

And from here I get an equation for the output mode of the cavity mode, output optical field. That is a_{out} is equal to a_{in} plus square root of κ a . This relation is known as the input-output relation. And it is a very useful relation because, if we can solve for the dynamics of the cavity mode a , then we can predict the observables in the cavity output. In fact, we can represent it in by diagram here.

(Refer Slide Time: 49:16)

So we have this Fabry-Perot cavity where one of the mirror is perfectly reflecting and its other mirror is partially transmittive. So input is incident here and then output is the reflected part inside the cavity. And inside the cavity there is a cavity mode is there. Then this is circulating mode is there and it decays at the rate κ . Now if κ is equal to 0 that means cavity decay rate is 0.

Then you immediately see that whatever is getting incident that is going to get reflected. On the other hand, if κ is not equal to 0, then the as you can see that the output is the sum of the incident field reflected at the cavity entrance and a contribution emanating from the cavity mode is given by this part. Please note that here this cavity mode, the A is a function of a_{in} as is evident from this equation here.

(Refer Slide Time: 50:43)

• Slide

$$\begin{aligned} \dot{\hat{a}} &= -i\omega_0 \hat{a} - \frac{\kappa}{2} \hat{a} + \Omega_{\text{drive}} e^{-i\omega_L t} - \sqrt{\kappa} a_{\text{in}} \\ &= -i\omega_0 \hat{a} - \frac{\kappa}{2} \hat{a} - \underbrace{\sqrt{\kappa} \left[a_{\text{in}} - \frac{\Omega_{\text{drive}} e^{-i\omega_L t}}{\sqrt{\kappa}} \right]}_{\tilde{a}_{\text{in}}} \end{aligned}$$

Finally, let us derive an expression for the drive coupling parameter Ω_{drive} which is the amplitude for the laser drive. When we are driving the Fabry-Perot cavity externally, we can use input output relation to work out an expression for Ω_{drive} . To do that, let us begin with this equation for the optical mode, cavity mode.

That is a dot is equal to minus $i\omega_0 \hat{a} - \frac{\kappa}{2} \hat{a} + \Omega_{\text{drive}} e^{-i\omega_L t} - \sqrt{\kappa} a_{\text{in}}$. This equation we can write in a little bit different form, let me write it. Minus $i\omega_0 \hat{a} - \frac{\kappa}{2} \hat{a} + \Omega_{\text{drive}} e^{-i\omega_L t} - \sqrt{\kappa} a_{\text{in}}$. And let me write square root of $\kappa a_{\text{in}} - \frac{\Omega_{\text{drive}} e^{-i\omega_L t}}{\sqrt{\kappa}}$ to the power minus $i\omega_L t$.

Let me define this parameter as the new input noise operator \tilde{a}_{in} and it includes the classical laser drive.

(Refer Slide Time: 52:03)

$$\dot{\hat{a}} = -i\omega_0 \hat{a} - \frac{\kappa}{2} \hat{a} - \sqrt{\kappa} \tilde{a}_{in}$$

$$-i\omega a(\omega) = -i\omega_0 a(\omega) - \frac{\kappa}{2} a(\omega) - \sqrt{\kappa} \tilde{a}_{in}(\omega)$$

$$\Rightarrow a(\omega) = \frac{\sqrt{\kappa} \tilde{a}_{in}(\omega)}{i(\omega - \omega_0) - \frac{\kappa}{2}}$$

And with this equation, so let me rewrite again. We have a dot is equal to minus i omega 0 a minus kappa by 2 a minus square root of kappa a tilde in. Now if I go over to the frequency domain, that means if I take the Fourier transformation, immediately I can get this equation, minus i omega a of omega. These are all operators. Let me do not write the hat term all the time.

So you understand that these are anyway quantum operators. We have minus i omega 0 a of omega minus kappa by 2 a of omega minus square root of kappa a tilde in of omega. From here you can immediately get the expression for a omega. That would be square root of kappa a tilde in of omega i omega minus omega 0 minus kappa by 2.

(Refer Slide Time: 53:05)

$$\Rightarrow \frac{\tilde{a}_{out}}{i(\omega - \omega_0) - \frac{\kappa}{2}}$$

Input-out relation $(a_{out} = a_{in} + \sqrt{\kappa} a)$

$$\tilde{a}_{out} = \tilde{a}_{in} + \sqrt{\kappa} a$$

where $\tilde{a}_{out} = a_{out} - \frac{\Omega_{drive}}{\sqrt{\kappa}} e^{-i\omega t}$

So if we now rewrite this input-output relation, let me rewrite input output relation for the new variable. We have this input output relation a_{out} is equal to a_{in} plus square root of κa . This we can write for our new variable says \tilde{a}_{out} is equal to \tilde{a}_{in} plus square root of κa . And where this a_{out} is defined in a similar way that of \tilde{a}_{in} and \tilde{a}_{out} is equal to a_{out} minus ω_{drive} divided by square root of κe to the power minus $i \omega L t$.

(Refer Slide Time: 53:56)

$$\tilde{a}_{out}(\omega) = a_{in}(\omega) + \sqrt{\kappa} a(\omega)$$

$$\Rightarrow \tilde{a}_{out}(\omega) = \tilde{a}_{in}(\omega) \left[1 + \frac{\kappa}{i(\omega - \omega_0) - \frac{\kappa}{2}} \right]$$

$$\tilde{a}(\omega_L) = \tilde{a}_{in}(\omega_L) \left[1 + \frac{\kappa}{i\Delta - \frac{\kappa}{2}} \right]$$

If I take the Fourier transform of this relation, so I will get it in the frequency domain is $\tilde{a}_{out}(\omega)$ is equal to $\tilde{a}_{in}(\omega)$ plus square root of $\kappa a(\omega)$. Now we know the expression for $a(\omega)$ from here and if I put it in this expression, so I will be able to write $\tilde{a}_{out}(\omega)$ is equal to $\tilde{a}_{in}(\omega)$ into $1 + \kappa$ divided by $i(\omega - \omega_0) - \kappa/2$.

Let me evaluate this \tilde{a}_{out} at the laser frequency ω_L and \tilde{a}_{in} at ω_L would be equal to \tilde{a}_{in} evaluated at ω_L $1 + \kappa$ divided by $i(\omega_L - \omega_0) - \kappa/2$, where I have defined the detuning parameter as $\omega_L - \omega_0$.

(Refer Slide Time: 55:14)

$$\tilde{a}_{out}(\omega_L) = \tilde{a}_{in}(\omega_L) \left[1 + \frac{\kappa}{i\Delta - \frac{\kappa}{2}} \right]$$

$$\Delta = \omega_L - \omega_0$$

$$\tilde{a}_{out}(\omega_L) = \frac{a(\omega_L)}{\sqrt{\kappa}} \left(i\Delta + \frac{\kappa}{2} \right)$$

And again what I can do, we can write this a tilde in omega L in terms of a of omega, because we have this expression. From here I can write it in terms of a of omega and if I put it there, so I will get, so this is a tilde out, I will get an expression for a tilde out. It is very simple to work it out, just a few step and if you do it, you will get it as a of omega L divided by square root of kappa i delta plus kappa by 2, okay.

So this expression now we are going to utilize because this allows us to express the conservation of energy by equating the input power to the outgoing power.

(Refer Slide Time: 56:17)

$$P_{in} = \hbar\omega_L \langle \hat{a}_{out}^\dagger \hat{a}_{out}(\omega_L) \rangle$$

$$= \hbar\omega_L \left(\Delta^2 + \frac{\kappa^2}{4} \right) \langle \hat{a}_{in}^\dagger(\omega_L) \hat{a}_{in}(\omega_L) \rangle$$

$$\dot{a} = -i\omega_0 a + \Omega_{drive} e^{-i\omega_L t} - \frac{\kappa}{2} a - \sqrt{\kappa} a_{in}$$

So input power P in has to be equal to the outgoing power that is equal to h cross omega L a dagger out plus a out and evaluated of course at the frequency of the laser that is omega L. Both these quantities a dagger as well as a, that is evaluated at omega

L. And because we have this expression for a tilde out, so from here I have h cross omega L. You can see that I will get del square plus kappa square by 4.

And we will have a dagger evaluated at omega L a of omega L. This is what I get. Now to go further, let me first do one thing. Let me take the equation for the cavity mode once again. So I have a dot is equal to minus i omega 0 a plus omega drive e to the power minus i omega L t minus kappa by 2 a minus square root of kappa a in.

(Refer Slide Time: 57:47)

Handwritten equations:

$$\dot{a} = -i\omega_0 a + \Omega_{drive} e^{-i\omega_L t} - \frac{\kappa}{2} a - \sqrt{\kappa} a_{in}$$

$$a = \tilde{a} e^{-i\omega_L t} \quad a_{in} = \tilde{a}_{in} e^{-i\omega_L t}$$

$$\dot{\tilde{a}} = i\Delta \tilde{a} + \Omega_{drive} - \frac{\kappa}{2} \tilde{a} - \sqrt{\kappa} \tilde{a}_{in}$$

In the steady state:

$$\langle \tilde{a} \rangle = - \frac{\Omega_{drive}}{i\Delta - \frac{\kappa}{2}}$$

To get rid of this parameter explicit time dependence, so I apply the usual trick. I go to the change of variable. a I take it as I take a is equal to A tilde e to the power minus i omega L t and a in I take it as a in tilde e to the power minus i omega L t. So if I do that I will be able to get an equation for a in terms of a tilde.

So a tilde dot is equal to i delta a tilde plus omega drive minus kappa by 2 a tilde minus square root of kappa a tilde in. And from here in the steady state I can get the steady state value of a tilde. In the steady state I will have a tilde, average value of a tilde would be equal to minus omega drive divided by i delta minus kappa by 2.

(Refer Slide Time: 58:55)

$$|\langle \tilde{a} \rangle|^2 = |\langle a \rangle|^2 = \frac{|\Omega_{\text{drive}}|^2}{\Delta^2 + \frac{\kappa^2}{4}}$$

$$\langle \hat{a}^\dagger(\omega_L) \hat{a}(\omega_L) \rangle = |\langle a \rangle|^2 = \frac{|\Omega_{\text{drive}}|^2}{\Delta^2 + \frac{\kappa^2}{4}}$$

$$P_{\text{in}} = \frac{\hbar \omega_L}{\kappa} |\Omega_{\text{drive}}|^2$$

And therefore, as you can see if I take the mod square of a tilde square that is exactly equal to mod of average of a square and that is equal to omega drive mod square divided by delta square plus kappa square by 4. So therefore, what we have here is this that a dagger of omega L a of omega L is equal to average of this quantity and this is equal to simply the one that let me again right here. It is this.

So this is what I have. So therefore, we will obtain P in is equal to h cross omega L. Okay, let me show you the expression here once again. So we have this. We now got this expression. So it will be h cross omega L divided by kappa omega drive mod square because this particular term is getting cancelled because of this term and we have this expression for input power.

(Refer Slide Time: 1:00:23)

$$\langle \hat{a}^\dagger(\omega_L) \hat{a}(\omega_L) \rangle = |\langle a \rangle|^2 = \frac{|\Omega_{\text{drive}}|^2}{\Delta^2 + \frac{\kappa^2}{4}}$$

$$P_{\text{in}} = \frac{\hbar \omega_L}{\kappa} |\Omega_{\text{drive}}|^2$$

$$\Rightarrow |\Omega_{\text{drive}}| = \sqrt{\frac{\kappa P_{\text{in}}}{\hbar \omega_L}}$$

And from here we can write an expression for the drive amplitude, laser drive amplitude. That would be $\text{mod of } \omega \text{ drive is equal to square root of } \kappa P \text{ in divided by } \hbar \text{ cross } \omega L$. This is an expression which is worth remembering and it will be useful for our discussion on cavity optomechanics in the next class. Let me stop here for today. In this lecture, we discussed how quantum Langevin noise affects the optical mode of a Fabry-Perot cavity.

This led us to the discussion of input-output relation. We applied this input output relation to derive an approximate expression for the laser drive amplitude. So we are now well equipped with all the tools to discuss quantum cavity optomechanics in the next class. So see you in the next class. Thank you.
