**Relations Among Yarn Count  $t$ , Twist  $Z$ , Packing Density And Diameter  $D$**

Today's lecture is oriented to the yarn strength as a stochastic process. It is known from practical experiences from textile laboratories and so on, that the mean value of yarn strength as well as yarn breaking strength and coefficient of variation of yarn strength are changed in relation to gauge strength which we use for making machines; why? It is a theme of our today's lecture.

(Refer Slide Time: 00:27)

(Refer Slide Time: 01:19)

Bohuslav Neckář and Dipayan Das, TU Liberec, Dept. of Textile Technology  
**YARN STRENGTH AS A STOCHASTIC PROCESS** 1

Usually yarn strength measurement is carried out at 500 mm gauge length. However, in practice, yarns experience stresses at different lengths. For example, during the post-spinning operations yarns of much longer than 500 mm length are stressed. Therefore, yarn strength measurement only at 500 mm gauge length is not sufficient. It is necessary to know yarn strength behavior at different gauge lengths precisely. Probably the first theoretical knowledge regarding strength-length relation in yarn was given by F. T. Peirce [*J. Textile Inst.* **17**, T355-368, 1926]. His model will be presented now.

**F. T. PEIRCE'S STRENGTH MODEL**  
Yarn strength is a random variable. The probability of breakage of one section of yarn of length  $l$  at a force  $S$  (strength) is  $F(S, l) \in (0, 1)$ .  $F(S, l)$  has a sense of the distribution function of strength  $S$  at length  $l$ . Hence the probability of survival is  $1 - F(S, l)$ .

We will speak about a Peirce's model which is relatively old and the easiest model and the second part of this theme I wrote in short comment our model which is much more difficult and need to have understood the tools from most special tools from theory of probability; especially from stochastic processes.

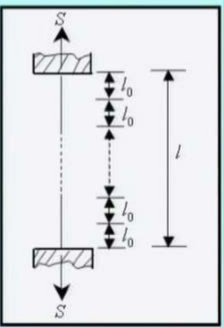

(Refer Slide Time: 03:21)

Bohuslav Neckář and Dipayan Das, TU Liberec, Dept. of Textile Technology  
**YARN STRENGTH AS A STOCHASTIC PROCESS** 2

**F. T. Peirce's 1<sup>st</sup> assumption:**  
Consider a longer yarn section of length  $l$  composed of  $n$  shorter sections of equal length  $l_0$  such that  $l = n l_0$ , as shown here. The probability of breakage of one section of length  $l_0$  is independent of the probability of breakage of any other section.

**F. T. Peirce's 2<sup>nd</sup> assumption:**  
The longer section must not break until any of  $n$  shorter sections breaks. This is the principle of the weakest-link theory.

Under these two assumptions, the following expression is valid.

Well, let us start the model according to Peirce. You know that yarn strength is a random variable; it is evident. The probability of breakage of one section of yarn of length  $l$  at a force  $s$  we can call under the symbol  $f(s, l)$ ;  $s$  is strength of yarn portion, yarn part, which

is studied  $l$  is gauge length which we use **ok**. So, that  $s$  is random variable:  $l$ , it is some parameter which, we know in which lengths we have our yarn which is the gauge lengths by our experiment. So, that  $f(s, l)$  has a sense as a distribution function of strength  $s$ , clear? At the lengths  $l$  and the probability of survival is  $1 - f(s, l)$  probability of break is  $f(s, l)$ . So, that the probability of the portion that does not break is  $1 - f(s, l)$ .

Well, let us imagine some yarn lengths  $l$  like this line is here  $f(n)$  lengths  $l$  between couple of this lengths  $l$  let's imagine divide it to  $n$  small lengths  $l_0$ ; then evidently  $l = n \cdot l_0$  as is shown. The probability of breakage of 1 section of lengths  $l_0$  is independent of the probability of breakage of any other section. This assumption is very important and it creates a basis of Peirce's model. We assume that the shorter the strength of short parts of the yarn lengths  $l_0$  are mutually independent.

You can imagine abstractly when you cut it your yarn to set of short segments lengths  $l_0$ . Then, you mix the segments together and then randomly you take one beside the other and glue it together you obtain new yarn. But, from point of view of break of strength your result will be the same because the strengths are not mutually dependent they are independent. Based on this assumption, the model is created

The second assumption is with the longer section must not break until any of  $n$  shorter sections breaks. This is the principle of the weakest link theory. Weakest link theory started from the idea of chain. Let us imagine a long chain; create it from links; one link beside the other. So, how is the strength of this long chain? This is equal as the strength of this link which have the minimum **links**; which is minimum quality, mechanical quality like inside.

(Refer Slide Time: 06:18)

Bohuslav Neckář and Dipayan Das, TU Liberec, Dept. of Textile Technology  
**YARN STRENGTH AS A STOCHASTIC PROCESS** 3

Probability of survival of each of  $n$  specimens, that is, probability of survival of the whole length  $l$

$$1 - F(S, l) = \underbrace{\left[ \underbrace{1 - F(S, l_0)}_{\text{Probability of survival of length } l_0} \cdot \underbrace{1 - F(S, l_0)}_{\text{Probability of survival of length } l_0} \cdots \underbrace{1 - F(S, l_0)}_{\text{Probability of survival of length } l_0} \right]}_{n \text{ times}}$$

$$= [1 - F(S, l_0)]^n = [1 - F(S, l_0)]^{\frac{l}{l_0}}$$

or  $[1 - F(S, l)]^{\frac{l}{l_0}} = [1 - F(S, l_0)]^{\frac{l}{l_0}}$  or  $F(S, l) = 1 - [1 - F(S, l_0)]^{\frac{l}{l_0}}$

The probability density function (PDF) of yarn strength at length  $l$  is given by  $f(S, l)$ . The PDF  $f(S, l)$  and  $F(S, l)$  are related as follows  $f(S, l) = \partial F(S, l) / \partial S$ . Analogically for length  $l_0$ ,  $f(S, l_0) = \partial F(S, l_0) / \partial S$ . Hence the PDF  $f(S, l)$  is

$$f(S, l) = \frac{\partial F(S, l)}{\partial S} = \frac{\partial}{\partial S} \left( 1 - [1 - F(S, l_0)]^{\frac{l}{l_0}} \right) = \frac{l}{l_0} [1 - F(S, l_0)]^{\frac{l}{l_0} - 1} \left[ \frac{\partial F(S, l_0)}{\partial S} \right]$$

$-f(S, l_0)$

Well, so, this is the principle of the weakest link theory. Under these two assumptions, the following expression is valid; it is shown here. What the sense of this equation  $F(S, l)$  is distribution function of strength on the yarn portion lengths  $l$  relatively long. Imagine this are long what is  $1 - F(S, l)$  is it a  $1 - F(S, l)$ .

Now, let us see the probability that these long lengths will not be destroyed will not be broken to our force  $S$ . So, is the distribution function and what is it lets imagine that this long lengths of the yarn is not broken; it means that the strength of the first link must be higher than our force  $S$ . How is the probability of this?  $1 - F(S, l_0)$ ; this is distribution function of the force  $F$  breaking force  $F$  by lengths of yarn  $l_0$  short lengths of the yarn  $l_0$  is not it. So, first link the probability that will not break is  $1 - F(S, l_0)$  **Ok.**

How it is with the second link? Same; the links are independent in our model now. So, the probability of the second link will not be destroyed, is also  $1 - F(S, l_0)$  clear? How is a probability that both will not be destroyed? You must multiply probabilities and so, we can go from first to the last link. How many links are there? **1 sorry n.**

So, we must multiply this quantity and times (Refer Slide Time: 08:35) is from first link from second link third and then to the end. So, that it is  $1 - F(S, l_0)^n$ , but  $n$  it was  $l$  by  $l_0$  is not it? So, it must be in the place of  $n$  we can write  $l$  by  $l_0$ ; we can obtain this equation as well as this equation  $F(S, l)$  distribution function of strength of our

yarn by lengths  $l$  it is  $1 - F(s, l)$  distribution function of same force  $s$  by short fiber segment  $l_0$  powered to  $l$  by  $l_0$

So, now we have summarized it how from distribution of the strength from short segments to obtain the distribution of strengths by longer portions of the yarn. Probability density function is principally clear? Question is now because probability density function it is a derivative of distribution function every times, is it not? So, we can say that the probability density function  $f(s, l)$ , it is derivative of the function  $F(s, l)$  by  $s$ . So, its partial because of the quantity is a parameter; it is not random quantity.

Well, analogically for length  $l_0$   $f(s, l_0)$  is the derivative function  $f(s, l_0)$  by  $l_0$  by the  $s$ . So, that the probability density function  $f(s, l)$  is the you made the derivative length left as well as right hand side and we obtain  $f(s, l)$  having this here, this here, then this (Refer Slide Time: 11:08) by this wasp  $d$  of short for short derivative for short analysis.

(Refer Slide Time: 11:16)

Bohuslav Neckář and Dipayan Das TU Liberec, Dept. of Textile Technology  
YARN STRENGTH AS A STOCHASTIC PROCESS

or  $f(s, l) = \frac{l}{l_0} f(s, l_0) [1 - F(s, l_0)]^{\frac{l}{l_0} - 1}$  This expression tells us the relation between the probability density functions of strengths measured at longer  $l$  and shorter  $l_0$  gauge lengths.

**F. T. Peirce's 3<sup>rd</sup> assumption:** Strength  $s$  of shorter specimens of length  $l_0$  follows Gaussian (normal) distribution with mean  $\bar{s}_0$  and standard deviation  $\sigma_0$ . The PDF of strength  $s$  of shorter specimen is shown by the following well-known expression

$$f(s, l_0) = \frac{1}{\sqrt{2\pi}\sigma_0} \exp\left[-\frac{(s - \bar{s}_0)^2}{2\sigma_0^2}\right]$$

The probability density function of the distribution of yarn strengths using long gauge length  $l$  is given by this equation clear. So, it is good to know because in short lengths  $l_0$  do not know for example, for 5 centimeter gauge lengths we can in laboratory do it; it is very difficult to say how it will be made. Some prediction how it will be for example, the distribution of yarn strengths using the yarn lengths  $l$  do not know for example, 5 meter or 3 meter or 500 meter very long so.

So, constructed instrument we have not in our laboratory we have not breaking machines where its possible to have gauge lengths I do not know, 5 meter or 500 meter it is sometimes very important because (( )) for example, in modern weaving rooms can be 2 – 3 meters which are programs; now 50 centimeter its standard gauge lengths based on standards in laboratory.

So, we can recalculate the probability density function or distribution function from short lengths right to short gauge lengths to the distribution on the long run the Peirce's. Assumed also a third assumption he said that then a short gauge lengths in our short gauge lengths 1 0 the distribution of strength of yarn strength is Gaussian normal Gaussian distribution and you know what is more frequent in India or Gaussian distribution normal distribution, but I hope you know both these parts, yes. Then, the probability density function  $F(S, l_0)$  must be given by known expression of probability density function in a Gaussian distribution.

(Refer Slide Time: 14:35)

Bohuslav Neckář and Dipayan Das TU Liberec, Dept. of Textile Technology

**YARN STRENGTH AS A STOCHASTIC PROCESS** 5

Then the distribution function is

$$F(S, l_0) = \int_{-\infty}^S f(Q, l_0) dQ = (1/\sqrt{2\pi}\sigma_0) \int_{-\infty}^S \exp\left[-(Q - \bar{S}_0)^2 / 2\sigma_0^2\right] dQ \quad (Q \dots \text{integ. var.})$$

From the theory of probability we know that the PDF of a variable  $u = (S - \bar{S}_0) / \sigma_0$  following the standardized Gaussian distribution is  $\varphi(u) = (1/\sqrt{2\pi}) \exp(-u^2/2)$  and its distribution function is  $\Phi(u) = \int_{-\infty}^u \varphi(v) dv = (1/\sqrt{2\pi}) \int_{-\infty}^u \exp(-v^2/2) dv$  Hence we can write

$$f(S, l_0) = (1/\sqrt{2\pi}\sigma_0) \exp\left[-(S - \bar{S}_0)^2 / 2\sigma_0^2\right] = (1/\sigma_0) \varphi\left(\frac{S - \bar{S}_0}{\sigma_0}\right)$$

$$F(S, l_0) = \int_{-\infty}^S f(Q, l_0) dQ = (1/\sqrt{2\pi}\sigma_0) \int_{-\infty}^S \exp\left[-(Q - \bar{S}_0)^2 / 2\sigma_0^2\right] dQ$$

$$v = (Q - \bar{S}_0) / \sigma_0, \quad Q = \sigma_0 v + \bar{S}_0, \quad dQ = \sigma_0 dv$$

$$= (1/\sqrt{2\pi}) \int_{-\infty}^{(S - \bar{S}_0) / \sigma_0} \exp(-v^2/2) dv = \Phi\left(\frac{S - \bar{S}_0}{\sigma_0}\right)$$

You can say in the moment that right hand side we have not 1 0; yes, explicitly we have not, but we have because on the 1 0 this is the 1 0 determinant sigma 0 standard deviation and mean value in our short length 1 0 therefore, implicitly it is there and the distribution function the distribution function  $F(S, l_0)$  is an integral of this. It is renamed 1 and the quantity because integrating variable must be added in the border. So, that using integral from our probability density function we obtain this here (Refer Slide Time:

14:55). We know that this integral this in normal distribution, Gaussian distribution, this it is an integral have not the primitive function in analytic form. That it is not possible to write it in an analytic form it is. So, it is called (( )) integral; under this theorem you can find it in some mathematical hand books and it takes it a lot of methods - how to numerically obtain the best approximation of this in general integral.

As you know, repetitive possible that we often write that so called standardized Gaussian distribution is not it; if our random quantity  $s$  of Gaussian distribution by the quantity  $s$  minus  $\bar{s}_0$ , it means, mean value mean value of our yarn strength in a short fiber lengths by standard deviation that is standard deviation it is a quantity  $u$  having standardized Gaussian distribution. You know from the theory of probability I think and this quantity  $u$  have probability density function is  $\phi(u)$  which is given by this expression. Also, very known from **lighter** age and this distribution function capital  $\Phi(u)$  it is integral from this to this here, the values exist some numerical method because probability integral (Refer Slide Time: 16:47). I said hence, we can write  $F(S, l_0)$  is this here or this here a very  $\Phi$  is a probability density function of standardized Gaussian distribution and for  $f$  capital  $F(S, l)$  distribution function we obtain using integral of there is such substitution we obtain this formula, but this is distribution function of standardized normal distribution which we called here as a  $\Phi$  if whole function is very known is in each book.

(Refer Slide Time: 17:51)

Bohuslav Neckář and Dipayan Das, TU Liberec, Dept. of Textile Technology  
YARN STRENGTH AS A STOCHASTIC PROCESS 6

What will be the distribution of strength of longer specimens (length  $l$ ) if the distribution of strength of shorter specimen (length  $l_0$ ) is Gaussian?

$$1 - F(S, l) = \left[ 1 - F(S, l_0) \right]^{\frac{l}{l_0}} = \left[ 1 - \Phi\left(\frac{S - \bar{S}_0}{\sigma_0}\right) \right]^{\frac{l}{l_0}} \text{ or } F(S, l) = 1 - \left[ 1 - \Phi\left(\frac{S - \bar{S}_0}{\sigma_0}\right) \right]^{\frac{l}{l_0}}$$

We already knew from slide number 4 that

$$f(S, l) = \frac{l}{l_0} \frac{f(S, l_0)}{\sigma_0} \left[ 1 - F(S, l_0) \right]^{\frac{l}{l_0} - 1} \text{ So we can write}$$

$$f(S, l) = \frac{l}{l_0} \frac{1}{\sigma_0} \phi\left(\frac{S - \bar{S}_0}{\sigma_0}\right) \left[ 1 - \Phi\left(\frac{S - \bar{S}_0}{\sigma_0}\right) \right]^{\frac{l}{l_0} - 1}$$

Evidently for  $l \neq l_0$ , the distribution of strength is not Gaussian. It is only Gaussian when  $l = l_0$ . This is graphically illustrated later.

This is distribution function of standardized Gaussian distribution. Well, now how it is with our distribution of yarn strength on the long lengths. We will derive  $1 - F(S, l)$  is  $1 - \Phi\left(\frac{s - \bar{s}_0}{\sigma_0} \sqrt{l/l_0}\right)$ . Using relations derived on earlier slide, we obtain that it is  $1 - \Phi\left(\frac{s - \bar{s}_0}{\sigma_0} \sqrt{l/l_0}\right)$  or  $F(S, l)$  is  $1 -$  this here.

If it is right that the distribution of strength in short lengths is also giving according to the Gaussian distribution then on the long gauge length  $l$  the distribution function is given by this expression. So, that we must have the distribution function of standardized Gaussian distribution and we calculate it in the point  $s - \bar{s}_0$  by  $\sigma_0$ .

(Refer Slide Time: 23:05)

Bohuslav Neckář and Dipayan Das TU Liberec, Dept. of Textile Technology  
YARN STRENGTH AS A STOCHASTIC PROCESS 7

Sometimes, strength  $S$  at gauge length  $l$  is transformed as follows: (This is not standardization, but **transformation**, and  $\bar{S}_0, \sigma_0$  correspond to gauge length  $l_0$ .)

$$u = \frac{(S - \bar{S}_0)}{\sigma_0} \quad S = \sigma_0 u + \bar{S}_0 \quad dS = \sigma_0 du \quad u \in (-\infty, \infty)$$

**1.) Probability Characteristics**

1A.) Distribution function  $G(u, l)$ :

Substituting  $u = \frac{(S - \bar{S}_0)}{\sigma_0}$  into  $F(S, l) = 1 - \left[1 - \Phi\left(\frac{S - \bar{S}_0}{\sigma_0}\right)\right]^{l/l_0}$ , we obtain,  $G(u, l) = 1 - [1 - \Phi(u)]^{l/l_0}$ .

1B.) PDF  $g(u, l)$ : From the theory of probability it is valid that  $g(u, l) du = f(S, l) dS$ . Then it is evident that

probability of  $u$       probability of  $S$

What we need to know? We need to know the mean value  $\bar{s}_0$  and standard deviation  $\sigma_0$  which have the short **analysis** for example, when we now we make some experiment there from this experiment we know that mean value on 5 centimeter lets imagine that the short lengths is 5 centimeter. So, we will use the gauge length short gauge length 5 centimeter  $l_0$  and from laboratory we obtain mean value of strength and standard deviation very standard method for evaluation of set of data.

We have  $\bar{s}_0$  and  $\sigma_0$  clear and now how is the value of distribution function and I do not know half meter gauge lengths conductively, we use half meter gauge lengths in yarn half meter gauge lengths  $l$  is 1 half meter how is this value. How is this distribution function is easy you must calculate this functions  $\Phi$  standardized distribution function in all points or points numerical points  $s - \bar{s}_0$  by  $\sigma_0$ .

So, is it clear how to apply it and we obtain distribution function for long lines. When we show through this way we when through this way we obtain the distribution function for one half meter gauge lengths we can compare it with experimental results take it on one half meter standard gauge lengths. But, we can through this we also obtain the distribution of strengths which probably we write for the gauge lengths 5 meter for example, and we have not chance experimentally obtained from laboratory. So, special breaking machine we have not, from this we need may be dance room for such breaking machine **ok.**

The distribution function you can see this over here that this function this distribution function (Refer Slide Time: 22:18) and the gauge lengths  $l$ ; another gauge lengths follows this expressions. So, that it is not Gaussian distribution; Gaussian is in this case only the distribution on the starting short lengths  $l$  is also  $l = 0$ .

We can also derive the distribution function which is derivative from one probability density function which is derivative from distribution function and so, we obtain such using this easy way **yes.** Because, with understanding in the moment I do not know what it is your value as  $\bar{s}$  and  $\sigma$  what is your value mean value of strength in short in short gauge lengths and what is your standard deviation.

Nevertheless we want to have some better picture how is also graphically proved explain how are the relations how is the change this of quantities of functions therefore, let's introduce some linear transformation which is here  $u$  is  $s - \bar{s} / \sigma$  when on the place of  $s$  breaking forces give the values from gauge lengths  $l = 0$  then it is standardized random quantity clear, but when on the place of  $s$  you use random quantities from general from another gauge lengths gauge lengths  $l$ , then I cannot call it as a standardizing then it is linear transformation **ok.**

For example, I have values from one half meter breaking that the strengths from one half meter and now I construct the quantities  $u$  random quantities  $u$  every times the strength from the yarn by lengths one half meter minus mean value mean value of mean strengths value by gauge lengths 5 centimeter by standard deviation by gauge lengths 5 centimeter by  $l = 0$  clear it is a linear transformation.

It is possible to rearrange our equation to a new a distribution function all distribution of function of  $s$  breaking force then distribution function of. So, defined linearly

transformed quantity name u and I obtain the distribution function g u 1 it is evident this from this derivation very short and very easy, but this g u r is 1 minus 15 upower to 1 by 1; 1 by 1 0 and the probability density function we obtain.

(Refer Slide Time: 26:09)

The slide, titled "YARN STRENGTH AS A STOCHASTIC PROCESS" by Bohuslav Neckář and Dipayan Das, shows the following derivations and graph:

$$g(u, l) du = f(S, l) dS = l/l_0 \cdot 1/\sigma_0 \cdot \varphi\left(\frac{u-l}{\sigma_0}\right) \left[1 - \Phi\left(\frac{u-l}{\sigma_0}\right)\right]^{-l/l_0} \frac{dS}{du} =$$

$$= l/l_0 \cdot 1/\sigma_0 \cdot \varphi(u) \left[1 - \Phi(u)\right]^{-l/l_0} \sigma_0 du$$

or

$$g(u, l) = l/l_0 \cdot \varphi(u) \left[1 - \Phi(u)\right]^{-l/l_0}$$

or

$$g(u, l) = l/l_0 \cdot \frac{1}{\sqrt{2\pi}} \cdot \exp(-u^2/2) \cdot \left[1 - \frac{1}{\sqrt{2\pi}} \int_{-\infty}^u (-v^2/2) dv\right]^{-l/l_0}$$

The graph shows  $g(u, l)$  vs  $u$  for various gauge lengths  $l/l_0$ : 1000, 300, 100, 30, 10, 3, 1 (Gaussian), 0.3, and 0.1. The curve for  $l/l_0 = 1$  is labeled "Gaussian", while others are labeled "Not Gaussian".

The above relation is graphically shown here.

Similarly, its derivative from this here it is shown here after derivative it was f this is under place F S l and this is from the s. So, that we obtain a probability density function n such from or especially because from the... because Gaussian distribution then capital phi is distribution function of standardized Gaussian distribution and we obtain we obtain these equation for practical application graph and we can show how is the probability density function for different lengths l.

If the lengths l is on the graph, a quantity u, linear transformed breaking force strength of the yarn and on the ordinate is the probability p d f probability density function g u for different gauge length is l if l is equal 1 0. So, that our experiment is also on our minimum gauge lengths 1 0 then we must obtain because it was our assumption; we must obtain Gaussian distribution. In this case, it is standardized Gaussian distribution this stick cover here this stick cover here.

When we have for example, length 50 centimeter and starting 1 0 was 5 centimeter then fifty centimeter is ten times longer gauge lengths. So, then one by one, 0 1 by 1 0 where is the curve for by 1 0 is 10 it is this curve here, it is this curve, clear? It is another distribution it is another distribution the position of this hat of probably curve of the

probability density function is going to the right hand side to a smaller values and a I can say thickness of this hat is a little smaller standard deviation is smaller as well as coefficient variation.

You can see that we can calculate it for different values 1 by 1 0 hereand it corresponds principally good to our laboratory experiences means when we use longer gauge length then the distributionhave the mean value is small and standard deviation is smaller too by the same products same yarn yes. So, you can see how it is you can also see thatthe curves this is right Gaussian distribution.

When we use very high value 1 by 1 0 it is also by our eyes to see thatthis curve is not Gaussian for example, this curve is not fully symmetric see it clear. So, its another distribution;its another type of distribution. Eachgauge lengththis have some other distribution only the lines gauge lengths lequal 1 0 have our starting Gaussian distribution.

(Refer Slide Time: 30:30)

Bohuslav Neckář and Dipayan Das TU Liberec, Dept. of Textile Technology  
**YARN STRENGTH AS A STOCHASTIC PROCESS** 9

**2.) Statistical Characteristics**

$\bar{u} = \int_{-\infty}^{\infty} u g(u, l) du$	}	$\sigma_u^2 = \overline{(u - \bar{u})^2} = \bar{u}^2 - \bar{u}^2$	}	Mean	Variance
$\bar{S} = \sigma_0 \bar{u} + \bar{S}_0$		$\sigma_s^2 = \overline{(S - \bar{S})^2} = \sigma_0^2 \sigma_u^2$			

$\sigma_s = \sqrt{\sigma_s^2}$  Standard deviation

Another important statistic is coefficient of variation (CV) as shown:  $v_u = \sigma_u / \bar{u}$  or  $v_s = \sigma_s / \bar{S}$

Another two oft-used statistics are:

**Skewness** (measure of lack of symmetry of the distribution of a dataset) as shown below

$$a = \frac{\overline{(u - \bar{u})^3}}{(\overline{(u - \bar{u})^2})^{3/2}} \quad \text{or} \quad a = \frac{\overline{(S - \bar{S})^3}}{(\overline{(S - \bar{S})^2})^{3/2}}$$

It is possible to evaluate also some statistical characteristics u bar which is even hereor ultimately s bar mean values which can bethen evaluate using this expression we can evaluate s square of standard deviation of this dispersion variants of uand using the this 1 also thevariants of s strength variants which is here then of course, standard deviation as a square root from dispersion variantvariants then we canevaluate.

(Refer Slide Time: 31:52)

Bohuslav Neckář and Dipayan Das TU Liberec, Dept. of Textile Technology 10

**YARN STRENGTH AS A STOCHASTIC PROCESS**

**Kurtosis** (measure of peakedness of a dataset relative to Gaussian distribution) as shown below

$$e = \left[ \frac{\overline{(u - \bar{u})^4}}{\left\{ \overline{(u - \bar{u})^2} \right\}^2} \right] - 3 \quad \text{or} \quad e = \left[ \frac{\overline{(S - \bar{S})^4}}{\left\{ \overline{(S - \bar{S})^2} \right\}^2} \right] - 3,$$

*Note: Clearly except skewness and kurtosis, other statistics for length  $l$  depend on the statistics for length  $l_0$ . The behaviors of these statistics as a function of the ratio of two gauge lengths  $l/l_0$  are shown in the figure.*

Another important statistic as for example, coefficient of variation  $v_u$  as well as  $s$  we can obtain also skewness using this expression here or this one as well as Kurtosis curve for probability density function this graph show different statistical quantities as a function of gauge lengths important line is two thick curves the mean value oh sorry the mean value is this curve it is shown that the mean value of strength is increasing of the gauge lengths is ratio 1 by 10 is decreasing and the standard deviation is decreasing too there is also the path for shorter analysis then 10 that is possible to go to another side, but for us is enough to understand how it from 10 to higher gauge lengths.

Well this all is nice, but it need to use a relatively know to nice numerical method by calculation today its principle possible nevertheless for people which are able to prepare some computer programmed some software for such evaluation Peirce's create it around nineteen thirty in that time do not exist computers and I must say that based on my meaning mister Peirce's was very junior and very high educated because this is was too complicated for to calculation this final values by hand only.

YARN STRENGTH AS A STOCHASTIC PROCESS

F. T. Peirce approximated the numerical form of the behaviors of  $\sigma_u$  and  $\bar{u}$  (thick lines) by the following theoretical relations

$$\sigma_u = \frac{\sigma_s}{\sigma_0} \equiv \left(\frac{l}{l_0}\right)^{-1/5}, \quad \bar{u} = \frac{\bar{S} - \bar{S}_0}{\sigma_0} \equiv 4.2 \left[ \left(\frac{l}{l_0}\right)^{-1/5} - 1 \right].$$

In another form

$$A = \bar{S}_0 - 4.2\sigma_0, \quad B = \sigma_0 l_0^{1/5},$$

$$\bar{S} = A + 4.2Bl^{-1/5},$$

He proved to construct some approximation equations and when you studied this material you can see how deep was education in theory of probability and properties of probability density functions and. So, on resulting equations which we which we obtain as a approximation of our way because.

YARN STRENGTH AS A STOCHASTIC PROCESS

**2.) Statistical Characteristics**

$\bar{u} = \int_0^{\infty} u g(u, l) du$	} Mean	$\sigma_u^2 = (\bar{u} - \bar{u})^2 = \bar{u}^2 - \bar{u}^2$	} Variance
$\bar{S} = \sigma_0 \bar{u} + \bar{S}_0$		$\sigma_s^2 = (\bar{S} - \bar{S})^2 = \sigma_0^2 \sigma_u^2$	

$\sigma_s = \sqrt{\sigma_s^2}$  Standard deviation

Another important statistic is coefficient of variation (CV) as shown:  $v_u = \sigma_u / \bar{u}$  or  $v_s = \sigma_s / \bar{S}$

Another two oft-used statistics are:

**Skewness** (measure of lack of symmetry of the distribution of a dataset) as shown below

$$a = \frac{(u - \bar{u})^3}{(u^2 - \bar{u}^2)^{3/2}} \quad \text{or} \quad a = \frac{(S - \bar{S})^3}{[(S - \bar{S})^2]^{3/2}}$$

We need for we need for mean value this integral we need for standard deviation over yarn than this here. So, this very difficult integral is not analytical I said it is Gauss integral. So, it was very difficult, but he found something which is relatively good

approximation in my book as well as in other books for example, cosigns structure of the yarn that polish book is compact how is the difference between the approximation original results and I can say that not practically too important. So, we can go; we can very well use following equations.

He said that  $\sigma_e$  which is  $\sigma_s$  by  $\sigma_0$   $\sigma_s$  is standard deviation of the strength by lengths  $l$  our lengths longer lengths  $l$   $\sigma_0$  is standard deviation by of yarn strength by gauge length  $l_0$  and that is ratio is  $l$  by  $l_0$  times minus  $1$  by  $5$  the second equation is the  $\bar{u}$  which is  $s^*$  minus  $\bar{s}$   $0$  mean value of yarn strength and the cosigns  $1$  minus mean value of yarn strength by gauge lengths at  $0$  by  $\sigma_0$  standard deviation of yarn strength of short lengths  $l_0$  therefore,  $0$  is four point two times  $1$  by  $l_0$  power to  $1$  minus by minus  $1$ .

We can also this result of mister Peirce's rearrange a flowing from some parameter  $a$  is  $s_0$  bar minus four point two times  $\sigma_0$  the other parameter  $b$  is  $c$  by  $0$  times  $1$   $0$  power to one by  $5$  and then  $\bar{s}$  is  $a$  plus four time four by two  $b$  times one power two minus one by  $5$  how to practically use this equations for example, you are you have studied some weaving process lets imagine in our modern weaving loom weft yarn where the I do not know free meter for example, long.

We need to have some information how is distribution of yarn strength by gauge lengths gauge lengths is this the lengths on which is on which we exponent our left yarn.

So, symbolically gauge length three meter its much possible is standard breaking machine, but you can same yarn study in your laboratory and you can study it for example, using one half meter standard gauge lengths. So, you can think my standard my short gauge lengths is one half meter  $l_0$  my long lengths  $3$  meters I observe the work in laboratory and I evaluate standard the values of yarn strength and what I obtain I obtain as  $s_0$  bar mean value of yarn strength by  $1$  half meter gauge length and standard deviation  $\sigma_0$  from our data know.

So, this two are known then can obtain a parameter  $a$  I can calculate the parameter  $a$  as well as the parameter  $b$  where on the place of  $l_0$  is now  $0$  point  $5$  meter our short lengths I able to calculate both and how is the mean how is the mean as strength by three meter length long gauge lengths you have these equations here.

And so on. So, that through this way is relatively easy possible to obtain the mean value and standard deviation and.

(Refer Slide Time: 40:02)

So, on to the gauge length we should do not measure based on the results which you measured this graph is one of graphs from work of our doctor dipayan das why it in the from here which he was university is not it.

The points here are experimental points it is an example from some yarn which of combed yarn seven point four from cotton it is the yellow point are experimental points based how we how we measured in our method we used 5 centimeter 5 centimeter gauge lengths as a shortest 5 centimeter was for us was for us the shortest 10 gauge length why use 5 centimeter because the small is gauge length must be longer than each fiber.

In other case, you do not measure the strength of the yarn then partly you measure strength of fibers when we use for example, 1 centimeter gauge lengths and lot of fibers you will have in both the jaws. So, it is not the strength of the yarn then the from fifty percent each strength of the fibers .

So, that we choose 5 centimeter as a short gauge lengths andah then we then we measure one beside other one portion 5 sentence second that and so on. So, we obtain lot of 5 centimeter lengths and. So, on and from this we evaluate also the strength on the

different are the different are the lengthsthe experimental points from different gauge lengths. Yellow based on the shortest it means 5 centimeter gauge lengthswe derivethe parameters which is necessary and we derive the red curves which are here these red curves show the Peirce's mean value in the relation tomean values measure experimental values and the second graph showthe standard deviation standard deviation which is measured the yellow points and the values constructed from the shortest gauge lengths.

Therefore, in this point 5 centimeter, it is 5 centimeter,15 millimeterthe experimental point as well as the red curve is in same point. Well, you can see principally this theoretical concept corresponds to the reality. Itcorresponds to the reality; nevertheless, some distances you can see the red curves are little under our experimentalis not itits typical for this equations why I want to say in our next lecture. So, in the moment thank you for your attention and the next lecture, we will continue it is notes to the possible modification of the Peirce's concept; thank you for your attention.
