

Power System Analysis
Prof. Debapriya Das
Department of Electrical Engineering
Indian Institute of Technology, Kharagpur

Lecture – 49
Symmetrical components

So next in that previous topic we have seen that your that 3 phase fault, but in that case our objective was mainly for z bus building algorithm and few numericals we have solved right, but question is that in the z bus that we have to have z bus matrix, so in anyway. So, today we will start the other thing that is your symmetrical component because symmetrical component is more important for your our fault studies, because most of the fault actually unsymmetrical or all unbalanced type of faults right therefore, symmetrical your what you call that symmetric unsymmetrical a symmetrical component will be that your is easier, I mean will be applicable for such kind of fault analysis.

(Refer Slide Time: 01:22)

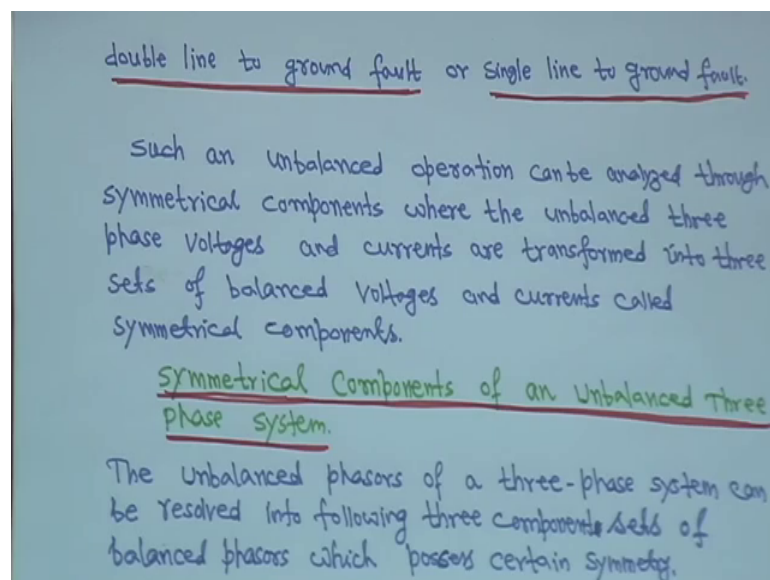

So, let us come to that your symmetrical component. So, generally in a balanced system analysis can be done on a single phase basis that we have seen also for three phase fault. The knowledge of voltage and current in one phase is sufficient to determine the voltage and current in other 2 phases because it is a balanced system. Real and reactive powers are three times the corresponding per phase values. So, for that is for balanced system, but when the system is unbalanced, the voltages, currents and the phase impedances are

in general unequal. So, unbalanced operation can result when loads are unbalanced, this is one thing. So, loads are unbalanced means that I mean all the three phase loads may be different, and this is more your what you call more applicable to the your distribution low voltage distribution system for example, in our country say 11 k v distribution system were or are in other parts of this world.

So, sometimes what happened that in three phase distribution loads are not balanced, this is one thing second thing in many places that from the same substation same feeder right single phase 2 phase or 3 phase loads are supplied. So, in that case your that things are become system become unbalanced and another aspect is that unbalanced system operation can result that is due to unsymmetrical fault.

(Refer Slide Time: 02:53)

For example, that your line to line fault that is called l l g right then double line to ground fault or single line to ground fault right. Such an unbalanced operation can be analyzed through symmetrical components, where the unbalanced three phase voltages and currents are transformed in to 3 sets of balanced voltages and currents called symmetrical components. So, another type of fault happens, but very rare that is your conductor opening suppose one phase conductor your opening means cut right. So, these are very rare, but question is that is also called open conductor your fault, but that we will see when we will go for unbalanced or unsymmetrical fault analysis. So, symmetrical components of an your unbalanced three phase system right this one. So, the unbalanced

phasors of a three phase system can be resolved in to the following three component sets of balanced phases, which possess certain symmetry; that means, for unbalanced phasor voltage or current right can we can dissolve in to following three component sets of balanced phasor and it has some symmetry that means.

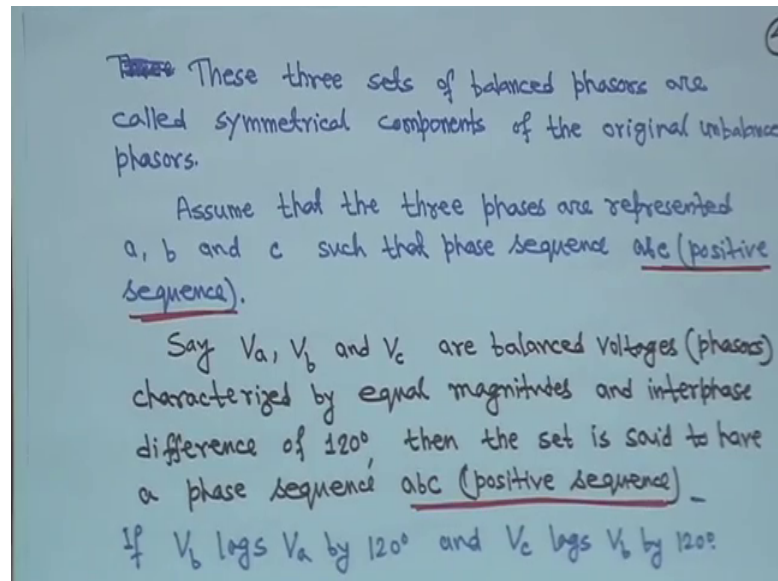

(Refer Slide Time: 04:18)

- 1.) A set of three phasors equal in magnitude, displaced from each other by 120° in phase, and having the same phase sequence as the original unbalanced phasors. The set of balanced phasor is called positive sequence component.
- 2.) A set of three phasors equal in magnitude, displaced from each other by 120° in phase, and having the phase sequence opposite to that of the original phasors. This set of balanced phasors is called negative sequence components.
- 3.) A set of three phasors equal in magnitude with zero phase displacement from each other. This set is called zero sequence components. The components of this set are all identical.

First thing is that is set of your three phasors equal in magnitude, displaced from each other by 120 degree in phase and having the same phase sequence as the original unbalanced phasors. And this set of balanced phase that is called positive sequence component. So, a set of three phasors equal in magnitude, but displaced from each other by 120 degree. The way we have solved the balanced system right and your and the; or the original unbalanced phasor this set of balanced phasor is called positive sequence component. Similarly a set of three phasors again equal in magnitude displaced again from each other by 180 degree or sorry 120 degree in phase, and having the phase sequence opposite to that of the original phasor I mean if for this one for positive sequence if it is a b c say for this one opposite it will be a c b sequence right and this set of balanced phasor is called negative sequence component.

And last one that is a set of 3 phases they are equal in magnitude with 0 phase displacement. There is no phase displacement between them, but they have equal magnitude from each and this set is called 0 sequence component. So, the component of this set are all identical, I mean they all are identical because they have equal magnitude.

(Refer Slide Time: 05:50)

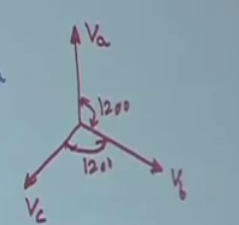

So, therefore, these three sets of balanced phasors are called symmetrical components of the original unbalanced phasor. So, assume that the three phasors are represented by a b c and such that phase sequence a b c is called positive sequence. So, this is this you know, this you know already we have done it right, this that three phase system. So, this is a b c. So, if a b c sequence this is actually positive sequence.

Now, say V_a V_b V_c are balanced voltages that is phasors, characterized by equal magnitude and interface difference of 120 degree this also you know. Then the set is said to have phase sequence a b c or positive sequence right, that is whatever we have studied little bit for solving say 3 phase transmission line or these that almost all are a b c all the a b c your what you call phase sequence. So, if V_b lags V_a by 120 degree, this you know and V_c lags V_b by 120 degree that also you know, then we can make this kind of your definition.

(Refer Slide Time: 07:11)

Assume V_a is reference phasor,
 $\therefore V_a = V_a ; V_b = \beta^2 V_a ; V_c = \beta V_a$
 Where the complex operator β is defined as:
 $\beta = e^{j120^\circ}$
 β has the following properties:
 $\therefore \beta^2 = e^{j240^\circ} = e^{-j120^\circ} = \beta^*$
 $(\beta^2)^* = \beta$
 $\beta^3 = 1$
 $1 + \beta + \beta^2 = 0$

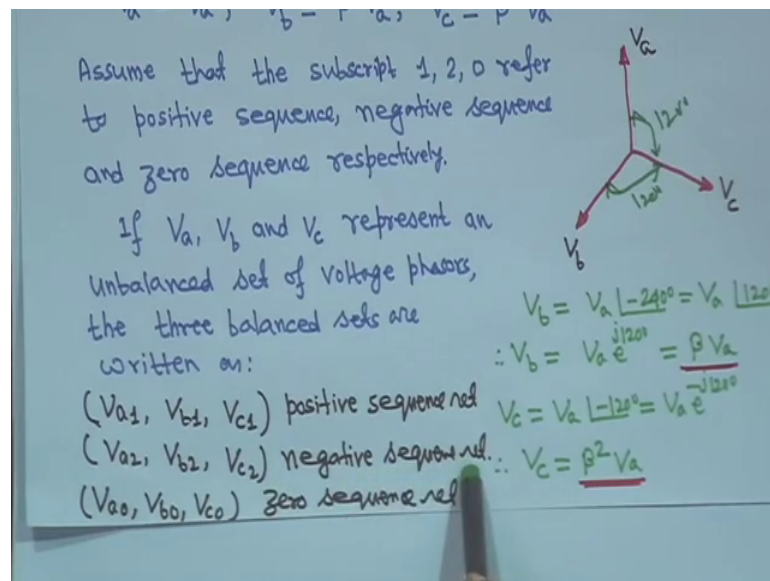

$V_b = V_a \angle -120^\circ$
 $\therefore V_b = V_a e^{-j120^\circ}$
 $\therefore V_b = \beta^2 V_a$
 $V_c = V_a \angle -240^\circ$
 $\therefore V_c = V_a \angle 120^\circ = V_a e^{j120^\circ}$

That is that assume your V_a is a reference phasor. Suppose if we put like this say V_a is a reference phasor. So, V_b lags from V_a here by 120 degree and V_c lags from V_a by 240 degree or otherwise V_c leads V_a by 120 degree. So, if we if I define like this say V_a is equal to V_a , a reference phasor V_b is equal to beta square V_a I am coming to that and V_c is equal to beta V_a right. Where the complex power a complex operated beta is defined as we have taken beta is equal to actually angle 120 degree. So, e to the power $j 120$ degree; that means, this beta has the following properties. Beta square beta is e to the power $j 120$ degree, then beta square e to the power $j 240$ degree is equal to it is e to the power minus $j 120$ degree that is actually is equal to beta conjugate. Similarly beta square conjugate is equal to beta. If you take beta square this conjugate that will become beta and beta cube is one because beta q means e to the power $j 360$ degree that is $\cos 360$ plus $\sin 360$. So, it is one right and $1 + \beta + \beta^2 = 0$ this conditions will be applicable now right. Now in this case that V_b is equal to V_a angle minus 120 degree here this figure.

That means V_b is equal to $V_a e$ to the power minus $j 120$ degree we can write like that therefore, V_b is equal to we can write beta square V_a because beta square is equal to e to the power $j 240$ degree is equal to e to the power minus $j 120$ degree. So, we can write V_b is equal to beta square V_a that is why we writing here V_b is equal to beta square V_a . Similarly V_c is equal to V_a angle minus 240 degree because these V_c lags from V_a

that is 240 degree. So, V_c is equal to V_a angle minus 240 degree that is we have given that your this V_c is equal to V_a otherwise V_c lags from here this thing or V_c leading V_a by 120 degree. So, same this can be written as V_c is equal to V_a angle 120 degree that is $V_a e^{j 120}$ degree, that is V_c is equal to βV_a ; that means, we are writing here V_c is equal to βV_a . So; that means, that means this $V_a V_b V_c$ this $V_b V_c$ we are putting in terms of a complex operator β , where β is equal to $e^{j 120}$ degree.

(Refer Slide Time: 10:03)

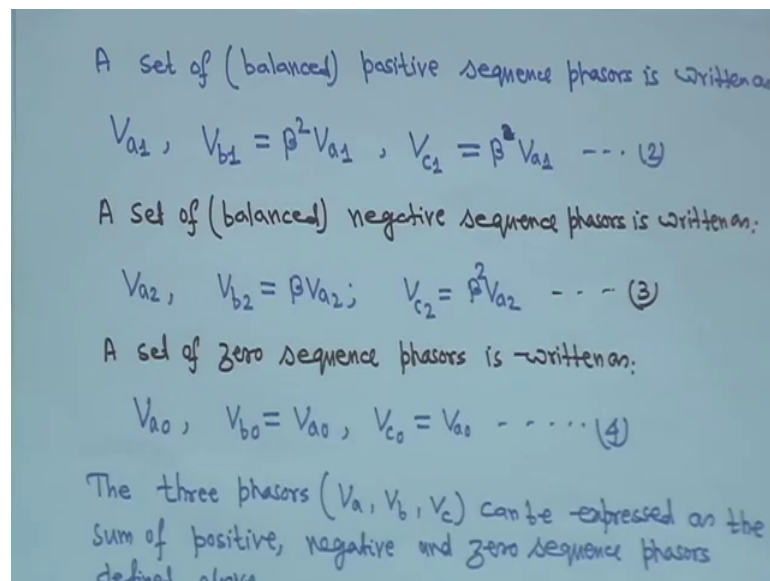

Next is if the sequence is a c b I mean it is if it is a negative sequence, right then V_a is equal to V_a now V_b will become βV_a and V_c will become $\beta^2 V_a$. Now sequence is a c b; that means, V_c lags from V_a by 120 degree this is your 120 degree and this one also your 120 degree. So, and V_b lags from V_a by 240 degree. Just whatever we have done previously it was β^2 now it will be β it was β now it will be β^2 therefore, V_b is equal to that is it is lags from V_a by angle minus 240 degree, that is actually V_a angle 120 degree. So, that is V_b is equal to $V_a e^{j 120}$ degree that is βV_a .

Similarly this V_c V_a angle minus 120 degree lags from V_a is equal to $V_a e^{-j 120}$ degree, that is V_c is equal to $\beta^2 V_a$. So, V_b is equal to βV_a here and V_c is equal to $\beta^2 V_a$ right. Assume now will assume now the subscript 1 2 and 0 refer to positive sequence, negative sequence and 0 sequence

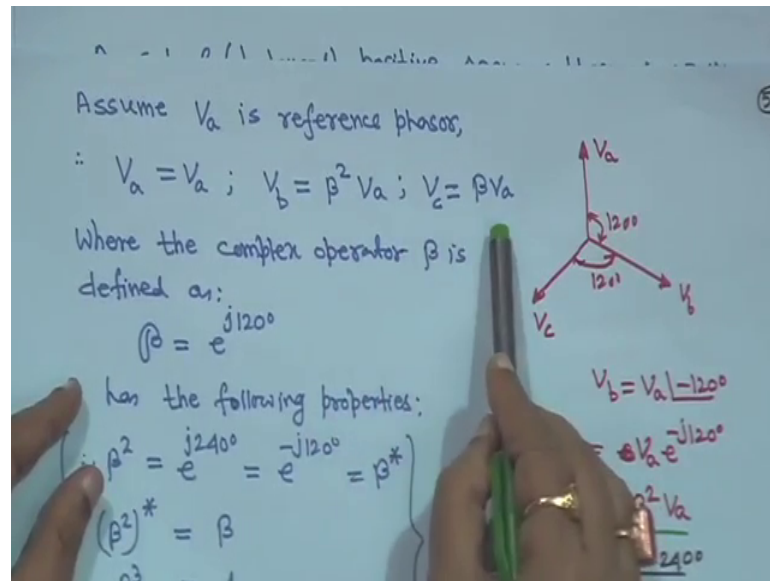

respectively. This is a this is actually convention everyone following this convention. So, if V_a, V_b, V_c represent an unbalanced set of voltage phasor, the three balance sets are written as. So that means, V_{a1}, V_{b1}, V_{c1} this is positive sequence set V_{a2}, V_{b2}, V_{c2} that is negative sequence set and V_{a0}, V_{b0}, V_{c0} that is 0 sequence set the this way we made it; that means, will come later, but let means V_a is equal to V_{a1}, V_{a2} plus V_{a0} . V_b is equal to V_{b1}, V_{b2} plus V_{b0} and V_c is equal to V_{c1} plus V_{c2} plus V_{c0} . So, these are that positive negative and 0 sequence set.

(Refer Slide Time: 10:12)

A set of balanced positive sequence phase now same way we will write the way we have seen a b c sequence here also, this is also balanced positive sequence phasor and sequence is your a b c. So, the way we wrote same way that it is we are not writing again V_{a1} is equal to V_{a1} , it is V_{a1} understandable V_{b1} will be beta square just one minute the same thing V_b will be is equal to your we have made it know V_b is equal to

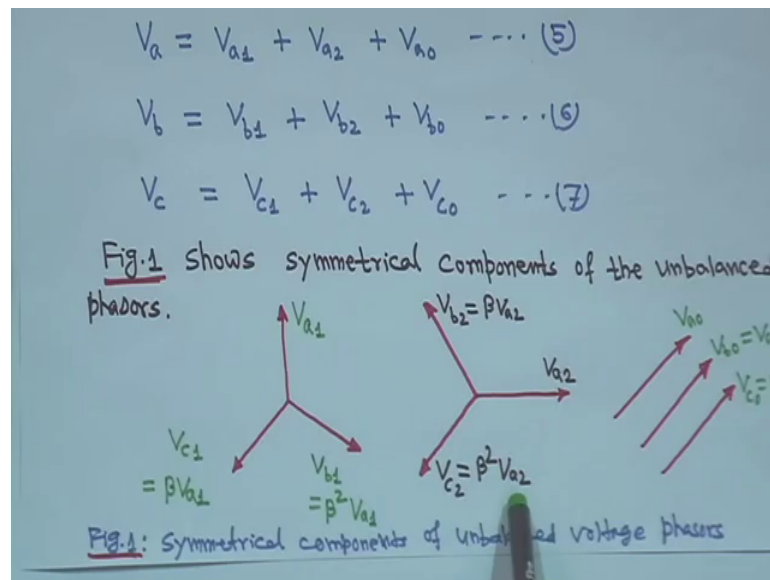

(Refer Slide Time: 12:41)

Beta square V_{a1} , and V_{c1} is equal to beta V_{a1} that is for a b c sequence this is also we are making it V_{a1} , V_{b1} , V_{c1} . So, here also V_{b1} will be beta square V_{a1} , and V_{c1} will be beta V_{a1} this here it is a b c sequence here is their positive sequence negative sequence and 0 this thing your 0 sequence component same thing will come.

So, for positive sequence that V_{a1} for phase a to this one, for phase v positive sequence V_{b1} will be beta square V_{a1} , for phase c positive sequence V_{c1} will be beta V_{a1} . Same your equations only you have to represent V_{a1} , V_{b1} , V_{c1} same philosophy. Similarly the same thing same will follow an a c b sequence that is a set of balanced negative sequence phasor, it is V_{a2} it will be V_{b2} is equal to beta V_{a2} and it will be V_{c2} is equal to beta square V_{a2} this is equation 3. Now a set of zeros sequence phasor they all are same. So, it will be V_{a0} , V_{b0} will be V_{a0} , and V_{c0} will be V_{a0} this is equation 2 3 and 4. Now this set these three phasors V_a , V_b , V_c can be expressed as the sum of positive negative and 0 sequence phasor defined above; that means, V_a is equal to V_{a1} plus V_{a2} plus your V_{a0} .

(Refer Slide Time: 14:16)

So, here we can write V_a is equal to V_{a1} plus V_{a2} plus V_{a0} this is equation 5. V_b is equal to V_{b1} plus V_{b2} plus V_{b0} equation 6, and V_c is equal to V_{c1} plus V_{c2} plus V_{c0} that is equation 7. Now this is your positive negative and 0 sequence your component. Here I have made this is V_{a1} . So, V_{b1} is equal to $\beta^2 V_{a1}$ and V_{c1} is equal to βV_{a1} this is negative sequence. V_{a2} at the reference one V_{c2} is equal to $\beta^2 V_{a2}$ and your V_{b2} is equal to βV_{a2} and this is your 0 sequence this is positive negative this is 0 sequence they are all in same phase right I mean through it is V_{a0} , it is V_{b0} is equal to V_{a0} V_{c0} is equal to V_{a0} because they have equal magnitude. So, these symmetrical components of your unbalanced voltage phasor. So, easily you can make this one

Now, let us your express equation 5 6 and 7 in terms of the reference.

(Refer Slide Time: 15:27)

Let us express eqn. (5), (6) and (7) in terms of reference phasors V_{a1}, V_{a2}, V_{a0} . Thus,

$$V_a = V_{a1} + V_{a2} + V_{a0} \dots (8)$$

$$V_b = \beta^2 V_{a1} + \beta V_{a2} + V_{a0} \dots (9)$$

$$V_c = \beta V_{a1} + \beta^2 V_{a2} + V_{a0} \dots (10)$$

Eqn. (8), (9) and (10) can be written in matrix form:

$$\begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ \beta^2 & \beta & 1 \\ \beta & \beta^2 & 1 \end{bmatrix} \begin{bmatrix} V_{a1} \\ V_{a2} \\ V_{a0} \end{bmatrix} \dots (11)$$

Phasor V_{a1} , V_{a2} and V_{a0} therefore, current will come that current also same philosophy that V_a is equal to V_{a1} plus V_{a2} plus V_{a0} . So, V_b is equal to your beta square V_{a1} plus beta V_{a2} plus your V_{a0} actually V_b is equal to just hold on let me show you that thing. So, this equation it is $V_b = V_{b1} + V_{b2} + V_{b0}$. So, V_{b1} is equal to your beta square V_{a1} and V_{c1} is equal to beta V_{a1} .

So, in this equation it is V_b is equal to your in this equation V_{b1} you substitute beta square V_{a1} , V_{b2} you substitute beta V_{a2} and V_{b0} is equal V_{a0} V_a your V_{b0} is equal to V_{c0} is equal to V_{a0} . So, V_{b0} is equal to V_{a0} . So, this is V_b similarly your V_c is equal to V_{c1} plus V_{c2} plus V_{c0} and your same way right you can make your this v or your V_{c1} is equal to beta V_{a1} and V_{c2} is equal to beta square V_{a2} , same way you put here that the way we have made it that your V_{b1} beta square V_{a1} , your V_{b2} is equal to beta V_{a2} same way you put it here V_{c1} , V_{c2} and V_{c0} is equal to V_{a0} ; that means, this will come beta v beta V_{a1} plus beta square V_{a2} plus V_{a0} ; that means, this V_a , V_b , V_c all actually represented by V_{a1} , V_{a2} , V_{a0} and the complex operator that is beta. So, this is equation 8 9 and 10, now this equation you put them in matrix form. So, it will be V_a V_b V_c and it will be 1 1 1 beta square beta one beta square 1 and V_{a1} V_{a2} V_{a0} . So, these three equations you put it in matrix form.

Next is this equation this equation only we can write.

(Refer Slide Time: 17:42)

or $V_p = AV_s \dots (12)$

where

$$V_p = [V_a \ V_b \ V_c]^T$$
$$V_s = [V_{a1} \ V_{a2} \ V_{a0}]^T$$
$$A = \begin{bmatrix} 1 & 1 & 1 \\ \beta^2 & \beta & 1 \\ \beta & \beta^2 & 1 \end{bmatrix} \dots (13)$$

From eqn.(12),

$$V_s = A^{-1}V_p \dots (14)$$

That V_p is equal to AV_s this way we write where V_p is equal to $V_a \ V_b \ V_c$ transpose right and V_s is equal to V_{a1}, V_{a2}, V_{a0} transpose and A is equal to that matrix $\begin{bmatrix} 1 & 1 & 1 \\ \beta^2 & \beta & 1 \\ \beta & \beta^2 & 1 \end{bmatrix}$ this is equation 13. So, this equation 12 this equation this equation can be written as V_s is equal to $A^{-1}V_p$ this is equation 14. So, the A^{-1} if you take the inverse of this matrix if you take the inverse of this matrix it will be.

(Refer Slide Time: 18:24)

The inverse of A is given by

$$A^{-1} = \frac{1}{3} \begin{bmatrix} 1 & \beta & \beta^2 \\ 1 & \beta^2 & \beta \\ 1 & 1 & 1 \end{bmatrix} \dots (15)$$

Complex conjugate of eqn.(13) can be given as:

$$A^* = \begin{bmatrix} 1 & 1 & 1 \\ (\beta^2)^* & \beta^* & 1 \\ \beta^* & (\beta)^* & 1 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 1 \\ \beta & \beta^2 & 1 \\ \beta^2 & \beta & 1 \end{bmatrix}$$

A inverse will become one third one beta, beta square one beta square beta 1 1 1, but you need not take directly that inverse I will show you one methodology that how one can remember at write basically A inverse is equal to one third A conjugate transpose I will come to that. So, if you take the complex conjugate of this matrix right that is your a matrix you take.

(Refer Slide Time: 18:50)

or $V_p = AV_s \dots (12)$

where $V_p = [V_a \ V_b \ V_c]^T$

$V_s = [V_{a1} \ V_{a2} \ V_{a0}]^T$

$A = \begin{bmatrix} 1 & 1 & 1 \\ \beta^2 & \beta & 1 \\ \beta & \beta & 1 \end{bmatrix} \dots (13)$

From eqn (12)

The complex conjugate of this matrix that is equation 13, then A conjugate will be this is 1 1 1 it will beta square conjugate it is beta conjugate it is one, beta conjugate beta square conjugate one. Earlier in the beginning I have given this is 1 1 1 that beta square conjugate is equal to beta at the beginning this has been given beta conjugate is equal to beta square that also given and one same is here. Beta conjugate is equal to beta square and beta square conjugate is equal to beta and this is one. So, first you take the A conjugate, after this this is actually A inverse if you take to that after this.

(Refer Slide Time: 19:31)

or $(A^*)^T = \begin{bmatrix} 1 & \beta & \beta^2 \\ 1 & \beta^2 & \beta \\ 1 & 1 & 1 \end{bmatrix} \dots (16)$

Using eqn (15) and (16), we get

$$A^{-1} = \frac{1}{3} (A^*)^T \dots (17)$$

Using eqn (14) and (15), we get

$$V_{a1} = \frac{1}{3} (V_a + \beta V_b + \beta^2 V_c) \dots (18)$$
$$V_{a2} = \frac{1}{3} (V_a + \beta^2 V_b + \beta V_c) \dots (19)$$
$$V_{a0} = \frac{1}{3} (V_a + V_b + V_c) \dots (20)$$

You take that transpose of this matrix that is A conjugate transpose, you take the transpose of this matrix if you take the transpose of this one. So, A conjugate transpose is equal to 1 beta beta square, 1e beta square beta and 1 1 1. So, using equation 15 and 16 this is your A inverse if you try to find out A inverse of your own it will become like that this is actually A inverse so; that means, A inverse actually one third A conjugate transpose; that means, if you know the a matrix a you take the A conjugate, then you take the transpose and divide it by 3, that is A inverse one third your A conjugate transpose this is equation 17. So, this is this is easy to remember if you know that you know the your what you call that A matrix.

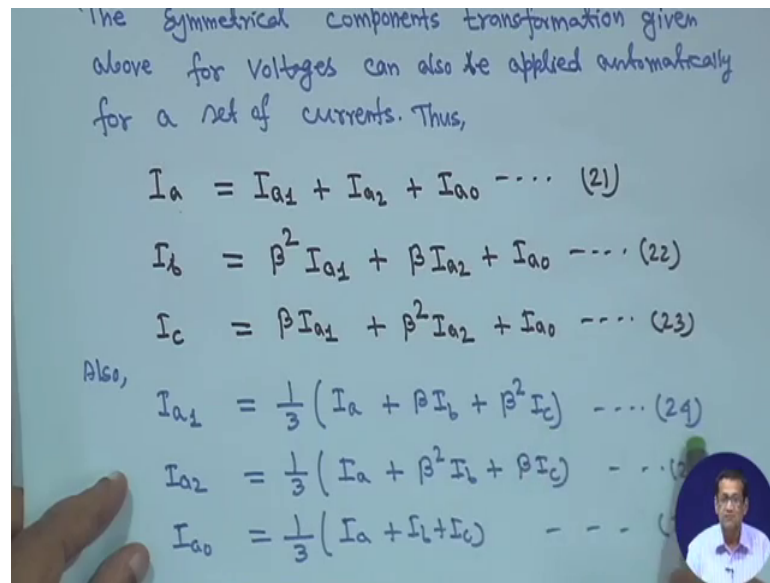

So, and A inverse will be one third, A conjugate transpose it is easy to remember. So, equation using equation 14 and 15 right we get, so equation 14. So, let me go back to equation 14. So, this is equation 14 that V s is equal to A inverse Vp and that means, if you that means, Vp is equal to your your V a, V b, V c and V s is equal to V a 1, V a 2, V a 0; that means, positive sequence component that V a 1 you can write one third because your one third is here right it is in that right because it is a inverse. So, one third is there. So, V a 1 is equal to one third V a plus beta V b plus beta square V c this is equation 18, and V a 2 is equal to one third V a plus beta square V b plus beta V c this is equation 19, and V a 0 is equal to one third in bracket it is V a plus V b plus V c this is 20. So, similar philosophy is applied to current same thing same positive negative 0 sequence component right.

(Refer Slide Time: 21:36)

The symmetrical components transformation given above for voltages can also be applied automatically for a set of currents. Thus,

$$I_a = I_{a1} + I_{a2} + I_{a0} \dots (21)$$
$$I_b = \beta^2 I_{a1} + \beta I_{a2} + I_{a0} \dots (22)$$
$$I_c = \beta I_{a1} + \beta^2 I_{a2} + I_{a0} \dots (23)$$

Also,

$$I_{a1} = \frac{1}{3} (I_a + \beta I_b + \beta^2 I_c) \dots (24)$$
$$I_{a2} = \frac{1}{3} (I_a + \beta^2 I_b + \beta I_c) \dots (25)$$
$$I_{a0} = \frac{1}{3} (I_a + I_b + I_c) \dots (26)$$

So, in this case you are the symmetrical component transformation given above for voltages can also be applied your automatically for a set of current same philosophy.

Therefore I_a is equal to I_{a1} plus I_{a2} plus I_{a0} this is equation 21. I_b is equal to same as same as voltages $\beta^2 I_{a1}$, plus βI_{a2} , plus I_{a0} and I_c is equal to βI_{a1} plus $\beta^2 I_{a2}$ plus I_{a0} . So, this is equation 23 same as voltage you will get I_{a1} that positive negative and 0 sequence component of say phase a, I_{a1} is equal to one third I_a plus βI_b plus $\beta^2 I_c$ this is equation 24. I_{a2} is one third in bracket I_a plus $\beta^2 I_b$ plus βI_c say it is 25, and I_{a0} is one third I_a plus I_b plus I_c this is equation 26. So, voltage and current same philosophy.

(Refer Slide Time: 22:39)

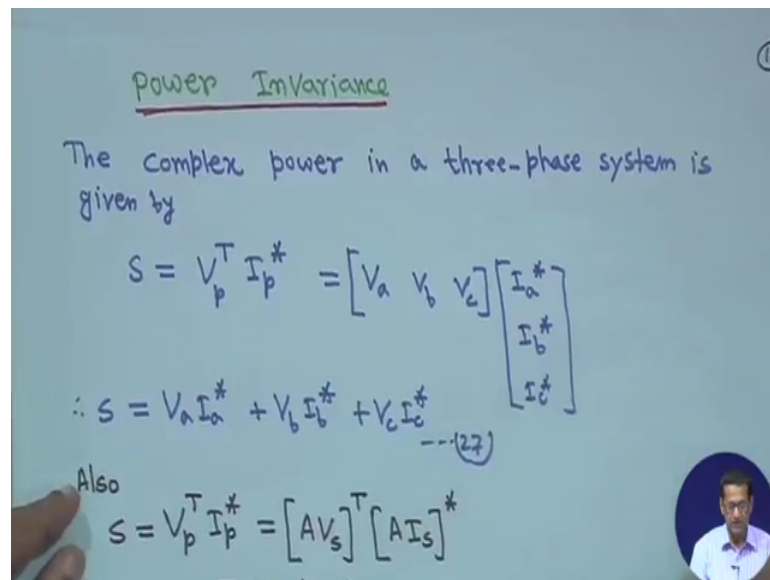

Power Invariance

The complex power in a three-phase system is given by

$$S = V_p^T I_p^* = \begin{bmatrix} V_a & V_b & V_c \end{bmatrix} \begin{bmatrix} I_a^* \\ I_b^* \\ I_c^* \end{bmatrix}$$

$$\therefore S = V_a I_a^* + V_b I_b^* + V_c I_c^* \quad \text{---(27)}$$

Also

$$S = V_p^T I_p^* = [AV_s]^T [AI_s]^*$$

Next is your power invariance. So, we have to show that that is the power equation also original thing and transformation both are matching. So, the complex power in a three phase system is given by we have already seen it before that s in general it is be your your what you call V transpose your I i conjugate. So, we can write s is equal to V_p transpose I_p conjugate that is V_p transpose is $V_a V_b V_c$ that we have given and I_p transpose actually I_a conjugate, I_p actually $I_a I_b I_c$. So, it is conjugate. So, I_a conjugate I_v conjugate I_c conjugate multiply you will get s is equal to $V_a I_a$ conjugate plus $V_b I_b$ conjugate plus $V_c I_c$ conjugate this is equation 27. Also s is equal to your V_p transpose I_p conjugate this one, we have seen before that V_p is equal to AV_s that we have defined let me show you once again that V_p is equal to AV_s that is equation 12. So, put here V_p is equal to AV_s similarly your same philosophy I_p also will become AI_s same philosophy I this is directly I have written, but philosophy remains same for voltage and current.

So, it will be AV_s transpose there AI_s conjugate. So, AV_s transpose means this one, V_s transpose then A transpose then AI_s conjugate; that means, A conjugate I_s conjugate this is actually equation 28, but AI_s I have not shown that, but understandable both are same voltage and current philosophy remain same. Now if you make it a matrix is known to you right a that means.

(Refer Slide Time: 24:27)

Now $A^T A^* = 3 \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$

$\therefore S = 3V_s^T I_s^* = 3V_{a1} I_{a1}^* + 3V_{a2} I_{a2}^* + 3V_{a0} I_{a0}^* = \text{sum of symmetrical component power}$

Sequence Impedances of Transmission Lines

Transmission line is a static device and hence the phase sequence has no effect on the impedance because currents and voltage encounter the same geometry.

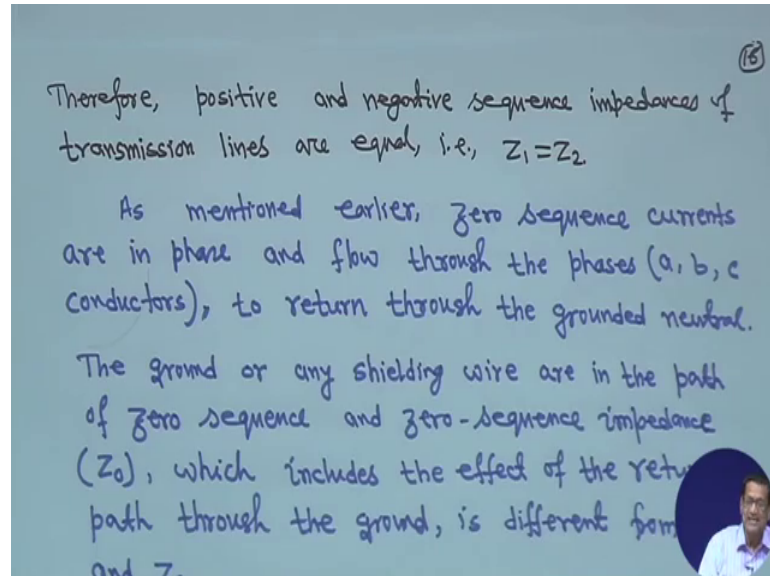

This is your A transpose A conjugate. If you multiply A transpose A conjugate it will be three in to an identity matrix that is 1 0 0 0 1 0 0 0 1. So, A transpose if you do so, it will be three in to an identity matrix; that means, s is equal to actually 3 V s transpose I s transpose; that means, it turns a A transpose A conjugate is a A transpose A conjugate is an identity matrix right multiplied by 3 of course, that means, it will become 3 V s transpose I s conjugate that is why we are writing that it is 3 V s transpose I s conjugate.

So, directly we are multiplying not writing this that V s transpose is V a 1, V a 2, V a 0 and I s transpose is I a 1, I a 2, I s 0. So, if you multiply it will be 3 V a 1, I o 1 conjugate plus 3 V a 2, I o 2 conjugate plus 3 V a 0, I a 0 conjugate sum of symmetrical components power. So that means, s is equal to whatever you get here equation 27 that is actually equation 29. They are their same I mean they have to be same right. So, now, sequence impedance of transmission lines. So, that is now we have to go for sequence impedance of each component, particularly the transmission line transformers then synchronous machine. So, just see how will make it. So, sequence impedances of transmission lines.

So, transmission line actually is a static device and hence the phase sequence has no effect on the impedance, because currents and voltage encounter the same geometry of the line. So, for the transmission line that it is basically again the again as I am saying there is a static device and hence the phase sequence has no effect on the impedance

because currents and voltage encounter the same geometry of the line therefore, positive and negative sequence impedance of transmission lines.

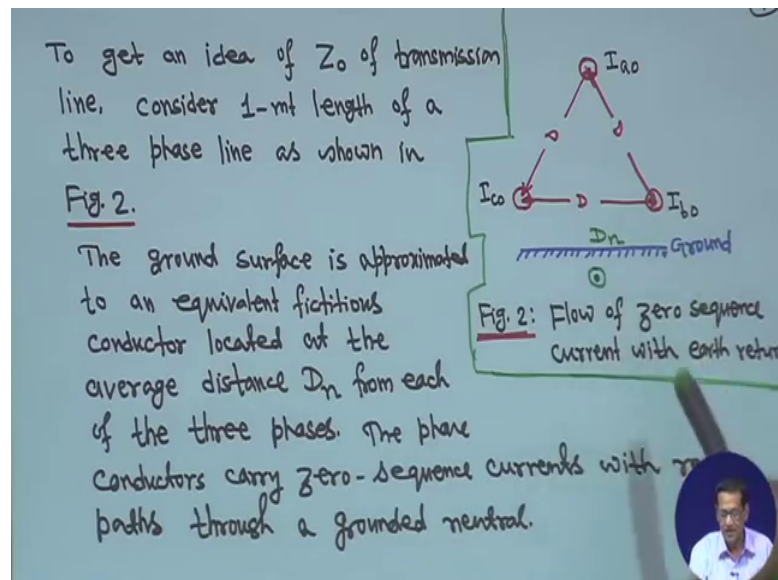

(Refer Slide Time: 26:35)

That is Z_1 is equal to Z_2 these 2 are equal for transmission line and, but as means we have discussed before that 0 sequence current are in phase with V_{a0} your I_{s0} same as voltage I_{s0} I_{v0} I_{c0} they are in phase and flow through the phases that is a b c conductors and to return through the grounded neutral. So, the ground or any shielding wire are in the path of 0 sequence and 0 sequence impedance Z_0 right.

So, transmission that means for the transmission line ground on any shielding wire right are in the path of 0 sequence and 0 sequence impedance that is Z_0 which includes the effect of the return path through the ground that is different from Z_1 and Z_2 . So, Z_0 sequence impedance for transmission line is different.

(Refer Slide Time: 27:37)

So, to get the get an idea, to get an idea of your Z_0 the 0 sequence impedance of the transmission line right you will consider only one meter length of a three phase life as shown in figure 2, I mean this figure right. So, this ground surface actually is approximated as an equivalent fictitious conductor located an average distance right from your what you call from each of the three phase. Actually this D_n I have shown it very close I should have shown a little bit away from this, but anyway the ground surface is approximated to and this is the ground, this is the ground right to an equivalent fictitious conductor and located at the average distance D_n from each of the three phases, so the this is an assumption.

So, the phase conductors carry 0 sequence current with written first through a ground neutral grounded neutral. So, for therefore, this is this is you have take a simple thing that is equilateral spacing distance is $D D D$, 0 sequence current here I_{a0} , I_{b0} , I_{c0} right and this 0 sequence current your what you call the phase conductors this is phase conductors carrying the 0 sequence current. We return path through a grounded neutral and this approximate and D_n actually that is distance as distance is taken from any phase to the neutral and average distance, this an approximation only to represent that 0 sequence impedance.

Thank you.
