Lecture - 21
Line Integrals

In today's lecture, we are going to start discussing about Line Integrals and Surface Integrals.

(Refer Slide Time: 00:27)

To start with we will first deal with line integrals. It talks about integrals of functions, of course which are defined on \mathbb{R}^n and taking values also in \mathbb{R}^n . And suppose on \mathbb{R}^n I have given a curve, I want to integrate the function over the curve. What exactly does it mean that is what I am going to explain now. So, suppose I have a function F defined on a subset A of \mathbb{R}^n to \mathbb{R}^n , where most of the time I am assuming any strictly bigger than one of course.

Usually they are called vector fields. That is given an element of capital A it assigns a vector which is $f x$. So, x goes to $F x$ which is a vector now. So, I can denote it sometime by $F_1 x, F_2 x, F_3 x$ the case n equals to 3, of course. Or I can also use the vector notation, that is $F_1 x \hat{i} + F_2 x \hat{j} + F_3 x \hat{k}$ the standard vector notation of \mathbb{R}^3 . Now, these are called the vector fields in space. Because, n equals to 3 accordingly we can define vector fields on plane also. That is the case equals to 2.

Now, in whatever I am going to do I will assume that capital F is a continuous function. Now, suppose I have a curve, what do you mean by a curve well it is a map c. Define on some closed interval a, b to \mathbb{R}^n I will usually work with n equals to 3. That is a space curve if I choose n equal to 2 I will call it a plane curve. Now that means, the curve is usually denoted by this also c t equals to x t, y t, z t. For example, I can look at this kind of a curve, that c of t equals to a cos t, a sin t and then t this is certainly curve.

So, that is a continuous function, so I will demand a property on c that is will assume. That means, I am looking at some specific kind of curve, which has certain analytic property. That would help in defining line integral. The property is that c prime t is a continuous function of t with this data.

(Refer Slide Time: 04:54)

Line integral of a vector field F over a curve c :

$$c: \int_C F \cdot ds = \int_a^b F(c(t)) \cdot c'(t) dt$$

where $c: [a, b] \rightarrow \mathbb{R}^3$ is a curve

$$c'(t) = (x'(t), y'(t), z'(t))$$

Example: $F(x, y, z) = (\cos z, e^x, e^y)$

$$c(t) = (1, t, e^t), \quad 0 \leq t \leq 2$$

Calculate $\int_C F \cdot ds$ | $c'(t) = (0, 1, e^t)$

Now, I am going to define the line integral of a vector field f over a curve c. What do I mean by this well the symbol for the line integral is integral over c F dot d s. I will explain what is the meaning of this symbol? The meaning is this following integral, integral a to b F of c t dot c prime t d t, where c from a, b to \mathbb{R}^3 is a curve. Of course, it is a curve with the assumption, which I have assumed that c prime is a continuous function.

Now, let us look at the definition again. Now, c t is a vector because, c is a curve in \mathbb{R}^3 throughout I am going to work with n equals to 3. So, it is always \mathbb{R}^3 , but there is no losing generality in saying that. So, c t is a vector it makes sense to apply F on that

vector, as a result F of $c(t)$ is a vector. Now, if I look at $c'(t)$ that is also a vector because, what is $c'(t)$. In the parametric notation it is just $x'(t)$ $y'(t)$ $z'(t)$, so given a value of t this is a vector F of $c(t)$ is also a vector.

So, it makes sense to talk about the dot product of these two vectors, as a result then I get a scalar valued function. And what is the domain of definition of the function that is F of $c(t) \cdot c'(t)$. While t varies in the closed interval a, b , so it defines a function from closed interval a, b to \mathbb{R} . And all because of all the continuity assumptions, which I am having, because my vector field is also a continuous function c' is continuous. That means, obviously, c is continuous it turns out that the integrand actually is a continuous function of t .

And hence it is integrable. So, we do the ordinary Riemann integration of this function. This is called the line integral of the function over the curve c . To understand the definition more clearly let me look at an example now. So, I will give you a particular vector field now, so the example I have in mind is given by. So, let me define the vector field as F of x, y, z , which is defined now as $\cos z$. Then e^{-x} , then e^{-y} this is certainly a vector field.

Now, I define a curve that is c of t . So, the curve is defined as $(1, t, e^t)$ and what is the variation of the parameter well. Let us say $0 \leq t \leq 2$ and I want to calculate integral over c of $F \cdot ds$. For that what is the first thing I need to do, I need to calculate what is F of $c(t)$? Well, the first thing I will calculate first is $c'(t)$, which seems to be easier $c'(t)$ is $(0, 1, e^t)$. You can see what I am doing, I am just differentiating each component with respect to t . Then I have to calculate what is F of $c(t)$?

(Refer Slide Time: 09:19)

$$\begin{aligned}
 F(c(t)) &= F(1, t, e^t) \\
 &= (\cos e^t, e, e^t) \\
 \int_0^2 F(c(t)) \cdot c'(t) dt & \\
 &= \int_0^2 (\cos e^t, e, e^t) \cdot (0, 1, e^t) dt \\
 &= \int_0^2 (e + e^{2t}) dt = e t + \frac{e^{2t}}{2} \Big|_0^2
 \end{aligned}$$

$$\begin{aligned}
 c(t) &= (x(t), y(t), z(t)) \\
 c'(t) &= \left(\frac{dx}{dt}, \frac{dy}{dt}, \frac{dz}{dt} \right) \\
 c'(t) dt &= dx \hat{i} + dy \hat{j} + dz \hat{k}
 \end{aligned}$$

So, F of $c(t)$ equals to F of $1, t, e$ to the power t , which then by definition of my vector field is cosine of e to the power t , then e , then e to the power t well that is F of $c(t)$. Now, I just look at this integral, integral 0 to 2 F of $c(t)$ dot c' prime t $d t$ equals to integral 0 to 2 cosine of e to the power t , e , e to the power t dot. Now, c' prime t , which I know is $0, 1, e$ to the power t then $d t$. I can calculate this vector product very easily, it is integral 0 to 2 e plus e to the power $2 t$ $d t$.

If I do this integration what I get is $e t$ plus e to the power $2 t$ divided by 2 . And then, I look at the limit 0 to 2 which you can very easily calculate. Just put the values of t , we get the line integral of the given vector field over the given curve. Now, in some of the calculus books you can see an alternative expression on the line integrals. That also I will explain now that given the curve $c(t)$, which is written as $x(t), y(t), z(t)$. I can write c' prime t as $dx dt, dy dt$ then $dz dt$. Now, this can be formally written as c' prime t $d t$ equals to dx .

(Refer Slide Time: 12:07)

The image shows a whiteboard with handwritten mathematical derivations. At the top, a vector field F is expressed as $F = F_1 \hat{i} + F_2 \hat{j} + F_3 \hat{k}$. Below this, the line integral $\int_C F \cdot ds$ is shown to be equal to $\int_a^b (F_1 \frac{dx}{dt} + F_2 \frac{dy}{dt} + F_3 \frac{dz}{dt}) dt$. The derivation is enclosed in a hand-drawn box. Below the box, it is noted that $f: \mathbb{R}^3 \rightarrow \mathbb{R}$ is a scalar field and f is differentiable. The gradient ∇f is given as $(\frac{\partial f}{\partial x}, \frac{\partial f}{\partial y}, \frac{\partial f}{\partial z})$. It is also stated that ∇f is continuous and C is a curve (with C' continuous).

And if the vector field f is given as $F_1 \hat{i} + F_2 \hat{j} + F_3 \hat{k}$ I am suppressing the variables. Of course, that you can see, it should actually be F_1 of x, y, z plus F_2 of x, y, z plus F_3 of x, y, z and so on. Plus $F_3 \hat{k}$ then integral over C $F \cdot ds$ that trans out to be integral a to b $F_1 dx$ plus $F_2 dy$ just taking the dot product plus $F_3 dz$. What it means is, it is integral a to b $F_1 dx dt$ plus $F_2 dy dt$ plus $F_3 dz dt$ and then dt . The formal expression of this kind you can see in calculus book written of line integrals.

It actually means the previous definition, which can be alternatively expressed as the last equality, which we have written in terms of the components of the function capital F that is the vector field. Now, for the as far as the calculation of line integration are concerned. You can see that, it can be very difficult if the integral ultimately which you are getting as F of $c(t)$ times $c'(t)$ if that is complicated. But, for certain functions the line integrals actually become much easier, now well go to those cases.

So, let us start with some simpler kind of line integrals. Suppose, I have a function f which is a function from \mathbb{R}^3 to \mathbb{R} , so this is a scalar field no longer a vector field, this is a scalar field, because the value of the function is a real number. Now, out of this scalar field, if f is differentiable I can manufacture a vector field out of this f the following way. That is the gradient of the function, which you are already accustomed with that is. So, the gradient of the function is $\nabla f = \frac{\partial f}{\partial x} \hat{i} + \frac{\partial f}{\partial y} \hat{j} + \frac{\partial f}{\partial z} \hat{k}$.

Now, assume that $\text{grad } f$ is continuous. So, I am putting two conditions on f that first of all it is differentiable. So, that I can talk about the gradient, second the gradient is a continuous function. So, it is a continuous vector field now, and suppose c is a curve. That means, c prime is continuous I am always using this property on the curve. Then I can always think about integral over c $\text{grad } f \cdot ds$.

(Refer Slide Time: 15:48)

$$\int_c \nabla f \cdot ds = f(x_1, y_1, z_1) - f(x_0, y_0, z_0)$$

$$c: [a, b] \rightarrow \mathbb{R}^3$$

$$\left. \begin{aligned} c(a) &= (x_0, y_0, z_0) \\ c(b) &= (x_1, y_1, z_1) \end{aligned} \right\}$$

$$\text{Proof: } h: [a, b] \rightarrow \mathbb{R} \quad c: \mathbb{R} \rightarrow \mathbb{R}^3$$

$$h(t) = f(c(t)) \quad f: \mathbb{R}^3 \rightarrow \mathbb{R}$$

$$f \circ c: \mathbb{R} \rightarrow \mathbb{R}$$

$$h'(t) = \nabla f(c(t)) \cdot c'(t)$$

$$\Rightarrow \int_c \nabla f \cdot ds = \int_a^b \nabla f(c(t)) \cdot c'(t) dt$$

$$= \int_a^b h'(t) dt = h(b) - h(a)$$

$$= f(c(b)) - f(c(a))$$

$$= f(x_1, y_1, z_1) - f(x_0, y_0, z_0)$$

Let us say c is from a, b to \mathbb{R}^3 . So, what is this integral I want to say it become something simpler, if c of a equals to x_0, y_0, z_0 and c of b equals to x_1, y_1, z_1 . Then it turns out that this is equal to f of x_1, y_1, z_1 minus f of x_0, y_0, z_0 . So, this you can actually see is a very neat analog of the second fundamental theorem of calculus. That integral of f prime is f b minus f a , it is more less an analog of that. And that is not just an accident. This result can actually be proved using the second fundamental theorem of calculus.

So, let us see how to prove this what I do is, I define a function h from a, b to \mathbb{R} . It is given by the formula h of t equals to f of c t . Notice, that c being a curve is a map from \mathbb{R} to \mathbb{R}^3 f being in a scalar field is a map from \mathbb{R}^3 to \mathbb{R} . So, as a result f compose c is a map from \mathbb{R} to \mathbb{R} , h is essentially f compose c . It is only the domain of c impose there that is why it is a map from a, b to \mathbb{R} . Now, h turns out to be differentiable function because of the assumptions which we have. And now I want to calculate what is h prime at t ?

Now, if I use that chain rule of several variable calculus, which you have learned already what I get is this is grad f at c t dot c prime t. This implies that integral over c grad f dot d s is nothing but, integral from a to b by definition grad f at c t dot c prime t equals to integral a to b h prime t d t. And now I can use fundamental theorem of calculus to get that this is h b minus h a. Apply this to the definition of h to get that this is f of c b minus f of c a, that is f of x 1, y 1, z 1 minus f of x 0, y 0, z 0. This is precisely what we wanted to prove.

(Refer Slide Time: 20:02)

Example:

$$F(x, y) = (y, x)$$

$$c(t) = (t^2, \sin^2 \frac{\pi}{2} t), \quad 0 \leq t \leq 1$$

$$F(c(t)) = (\sin^2 \frac{\pi}{2} t, t^2)$$

$$c'(t) = (2t, 2 \sin^2 \frac{\pi}{2} t \cdot \cos \frac{\pi}{2} t \cdot \frac{\pi}{2})$$

$$\int_C F \cdot ds = \int_0^1 (2t^2 \sin^2 \frac{\pi}{2} t + 2t^2 \sin^2 \frac{\pi}{2} t \cos \frac{\pi}{2} t \cdot \frac{\pi}{2}) dt$$

$$f(x, y) = xy \Rightarrow \nabla f(x, y) = (y, x) = F(x, y)$$

$$c(0) = (0, 0), \quad c(1) = (1, 1)$$

$$\Rightarrow \int_C F \cdot ds = \int_0^1 \nabla f \cdot ds = f(c(1)) - f(c(0)) = f(1, 1) - f(0, 0) = 1$$

Now, before observing some more things about this result. Let us see how does it make our life easier. So, I will try to calculate another line integral, in this case to make things simple. But, I will do is I will concentrate in the two dimensional case. So, let us take this force field that F of x y equals to y x, so this is s vector field. And now I take a curve, so let us take this curve c t equals to t to the power 9 sin 9 pi t by 2, where 0 lesser equals to t lesser equals to 1.

Now, suppose I want to calculate this line integral. So, first I need to know what is F of c t I will calculate that, this turns out to be easy this is sin 9 pi by 2 t. Then t to the power 9, then I need to calculate what is c prime t that is 9 t to the power 8. Then 9 sin 8 pi t by 2 times cosine pi t by 2 times pi by 2. And then I need to look at the line integral that is f dot d s that is integral 0 to 1 F of c t times c prime t. If I calculate this what is get is 9 t to

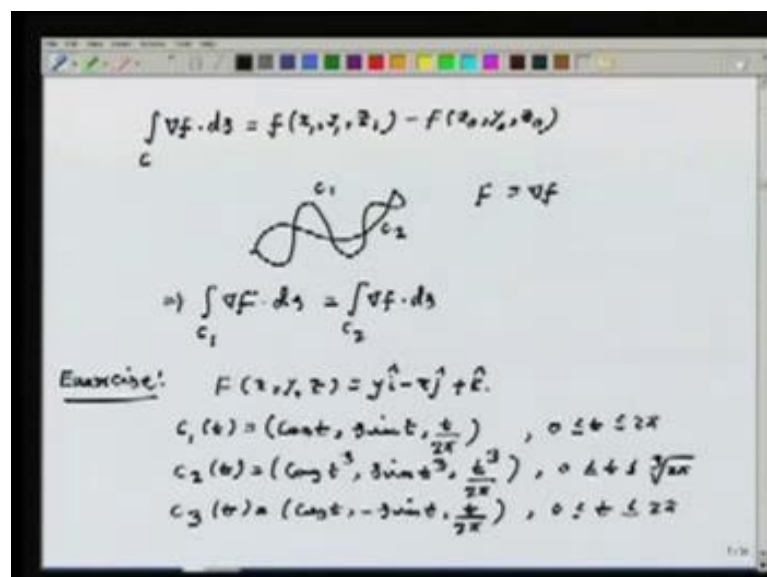

the power $8 \sin 9 \pi t$ by 2 plus $9 t$ to the power $9 \sin 8 \pi t$ by $2 \cos \pi t$ by 2 times π by 2 this whole thing $d t$.

Which you can see is quite a complicated integral, it might be very difficult to solve this calculate this integral explicitly. So, instead of that what I will do is, what we have observed in the previous case we will try to do that. That is ill try to realize this capital F as gradient of some function and that is very easy. I will just look at this function f of $x y$ equals to $x y$, this implies. Then that $\text{grad } f$ at $x y$ that is $\text{del } f$ $\text{del } x$, which is y comma $\text{del } f$ $\text{del } y$ which is x that is capital F at $x y$.

And then, I notice what is c_0 from the definition of curve it is clear that c_0 is $0, 0$. And what is c_1 that is again very clear, that this is 1 then $\sin \pi$ by 2 to the power 9 that is again 1 . So, by the previous formula it turns out that integral over c $F \cdot d s$ is nothing but, integral over c $\text{grad } f \cdot d s$. That means, it is f of c_1 minus f of c_0 , which then is f of $1, 1$ minus f of $0, 0$. But, I know my definition of f you just multiply the x coordinate and y coordinate. That means, f of $1, 1$ is 1 and f of $0, 0$ is 0 , that means the line integral is actually equal to 1 .

See, how complicated the previous integral was, but that does not really mean that the line integral is complicated to calculate. Once, we have used the fact that this given vector field capital F can be thought of as gradient of a scalar valued function. It becomes easy using the analog of the second fundamental theorem of calculus.

(Refer Slide Time: 24:37)

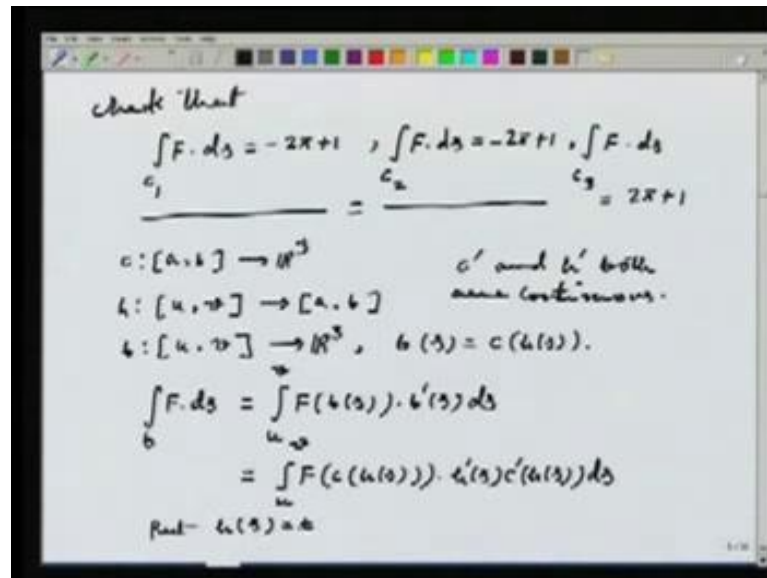

Now, let us go back to the observation. What I have proved is that $\int_C \text{grad } f \cdot ds = f(x_1, y_1, z_1) - f(x_0, y_0, z_0)$. It means that if I am integrating a gradient over a curve. Then the line integral does not really depend on the trajectory of the curve. It just depends on the initial point of the curve and the final point of the curve. Whatever way the curve joins those two points, the integrals are the same if the integrand is a gradient.

That is what follows from here, that if I have a point here and have a point here I can join it this way I can also join it this way you know. So, this is C_1 , this is C_2 and my capital F is some $\text{grad } f$. Then from the previous formula it follows that $\int_{C_1} \text{grad } f \cdot ds = \int_{C_2} \text{grad } f \cdot ds$, because the result depends on just the final point and the end point, final point and initial point.

But, in general that is not the case, if you have given a line integral of an arbitrary function, which is not really a gradient. Then the integral can depend on the trajectory of the curve that is it might matter how those two points are joined by a curve. So, I will give an exercise here, you can check it yourself consider the vector field F of x, y, z equals to $y \mathbf{i} - x \mathbf{j} + k$.

And let us take this curves, first one is C_1 I define it as $(\cos t, \sin t, t)$ by 2π . Then I define C_2 as $(\cos t^3, \sin t^3, t^3)$, then t^3 by 2π here $0 \leq t \leq \sqrt[3]{2\pi}$. Here $0 \leq t \leq \sqrt[3]{2\pi}$. And then, I define C_3 another curve that is $(\cos t, \sin t, t)$ by 2π where $0 \leq t \leq 2\pi$.

(Refer Slide Time: 28:05)

Now, just check the following that integral over c_1 $F \cdot ds$ that turns out to be equals to minus 2π plus 1 integral over c_2 $F \cdot ds$. That is minus 2π plus 1 and integral over c_3 $F \cdot ds$ that turns out to be 2π plus 1. Just calculate these integrals, it is essentially easy well observe this notice, that the first integral and the second integral they have different values. But, the final point is 2π that end the initial point is 0, they are joined by two different curves actually. And then it turns out that the integrals are different.

That means, in general it can happen that the line integral of a function over two different curves. But, joining the same points can be different. But, here something has also happened that integral of the function over c_1 . And integral of the function over c_2 has become equal, well this is not just a happy accident this happens. Because of the following fact, let me explain to it. So, suppose I have a curve c which is from a, b to \mathbb{R}^3 and suppose I have a map h , which is from u, v to a, b .

Assume that h and c has the property, that c' and h' both are continuous. Now, I can form a new curve call it b . So, b is a curve which is defined on u, v goes to \mathbb{R}^3 it is defined as $b(s) = c(h(s))$. Then b defines a new curve I want to know what is integral over b $F \cdot ds$, F is a given vector field I want to integrate f over b . Well, usually this new curve b which I have defined it is actually not new it is the same

curve. Because, the image is the same as the image of c , but the space of parameters now are coming from u, v . So, this is usually called a parameterization of the curve.

Now, I want to calculate what is the integral over b F dot ds , so what I do is I just write down the definition. So, this is integral from u to v F of b s dot b prime s ds . Now, I write it down it is integral u to v F of c of h s times I have to calculate what is b prime, that is h prime s times c prime at h s by chain rule times ds . Now, I do a change of variable to put h s equals to t . And then let us see where do the integral change, well if h s equals to t . Then the limits of integration will certainly change from h u to h v .

(Refer Slide Time: 32:27)

Handwritten mathematical derivation on a whiteboard:

$$\int_{h(u)}^{h(v)} F(c(t)) \cdot c'(t) dt \quad (\Rightarrow h'(s) ds = dt)$$

$$= \int_a^b F(c(h(s))) \cdot c'(h(s)) h'(s) ds = \int_c F \cdot ds$$

Example:

$$c_1 = (\cos t, \sin t, \frac{t}{2\pi}), \quad 0 \leq t \leq 2\pi$$

$$c_2 = (\cos t^3, \sin t^3, \frac{t^3}{2\pi}), \quad 0 \leq t \leq \sqrt[3]{2\pi}$$

$$h: [0, \sqrt[3]{2\pi}] \rightarrow [0, 2\pi]$$

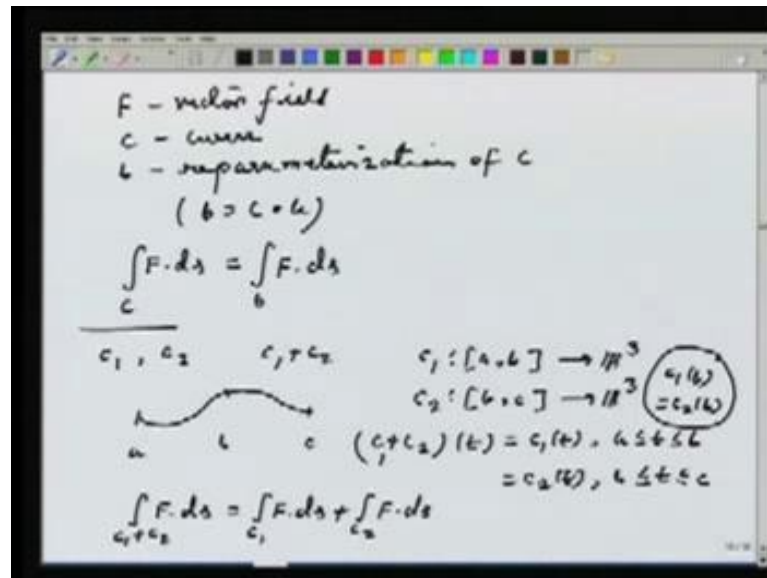

$$h(t) = t^3$$

$$c_2 = c_1(h(t))$$

And then F of c of t , because earlier I had F of c of h s times. Now, comes look at the integral again ((Refer Time: 32:48)) it comes to h prime s then c prime h s , but h s equals to t I am using the change of variable. It just changes to c prime t dt as h prime s ds is equals to dt , but now observe that h u is equals to a and h v equals to b . So, what I get is F of c t dot c prime t dt which is nothing but, the line integral of f over the curve c . Now, if you look at the previous example what was my c 1, c 1 was $\cos t$ $\sin t$, t by 2π where 0 lesser equals to t lesser equals to 2π .

And c 2 t was $\cos t$ cube $\sin t$ cube, then t cube by 2π where 0 lesser equals to t lesser equals to cube root of 2π . So, in this case what actually has happened is I have defined a map h from 0 and cube root of 2π to 0 to 2π given by h t equals to t cube. And then, my new curve, if I look at the relation c 2 is actually c 1 of h t .

(Refer Slide Time: 35:05)

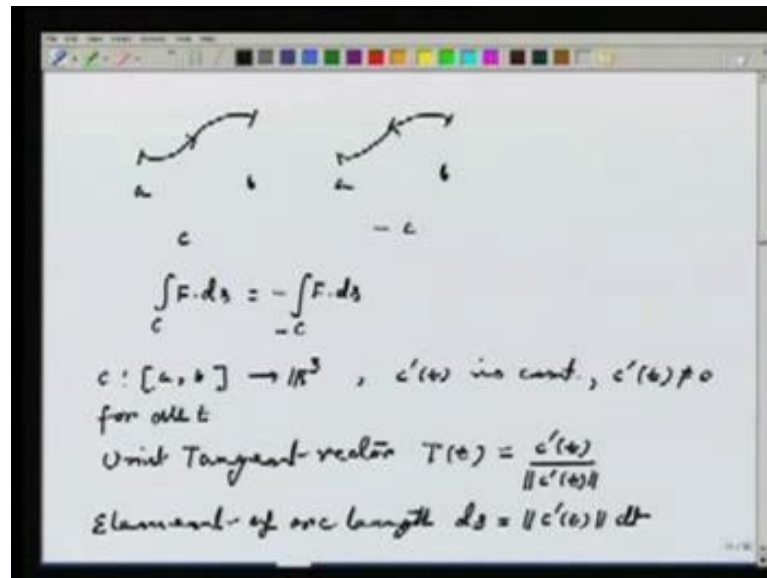

So, I will repeat again what we have observed here suppose, f is a vector field given, c is a given curve. B is another curve which is a reparametrization of c I have just defined, what does it mean to say that b is a parametrization of c . That means, the parameters spaces are given by some differentiable function. They are connected by some differentiable function h that is b equals to c compose h . Then integral over c F dot $d s$ that is integral over b f dot $d s$, that is the line integral does not change even if you change the parameterization of the curve.

Now, we will go to a different meaning of line integrals, but before that there are some elementary facts of line integrals, which can be easily proved. One is suppose we are given two curves c_1 and c_2 . Then you can talk about c_1 plus c_2 , what does it mean to say c_1 plus c_2 , so will just explain it by picture. Suppose this is c_1 it starts from a goes to b , then from b it goes by another curve let us say which is up to c .

So, the domain of c_1 is a, b and domain of c_2 is from b, c . Then from c_1 and c_2 I can talk about the curve c_1 plus c_2 , which is defined as this is equals to $c_1(t)$, if a lesser equals to t lesser equals to b and equals to $c_2(t)$. If b is lesser equals to t lesser equals to c only care has to be taken that $c_1(b)$ equal to $c_2(b)$ only then you can join the curve. In that case one can show that integral over c_1 plus c_2 F dot $d s$ that is equals to integral over c_1 F dot $d s$ plus integral over c_2 F dot $d s$. It follows just from the definition of the line integral.

(Refer Slide Time: 38:01)

Similarly, one can take the negative of a curve also just by changing the direction. Suppose this is my curve c , this is the initial point, this is the final point. Then, I can look at the same curve, but now in a reverse direction it goes this way let us say I can come back this way, see if this curve is c this is called minus c . And then using the definition of line integrals again one can check that integral over c $F \cdot ds$ that is minus integral of $F \cdot ds$, which is integrating the function over the curve minus c these two facts I will be using later they can be proved just by the defining properties of line integrals, it is nothing serious.

Now, let us shift to another geometric way of understanding the line integrals, so what we observe first is the following thing. Let us say c from a, b to \mathbb{R}^3 is the curve with the property of course, that c prime t is continuous, now I also assume that c prime t is non 0 for all t . So, it is an additional property I am throwing in, in most of the cases you will have this property satisfied, that the derivative of c is always non 0, then I can form the unit tangent vector I will call it T t capital T of t , this we know is defined by c prime t divided by norm of c prime t , so that it has unit length. Now, the element of arc length ds that is I know is norm c prime t dt .

(Refer Slide Time: 40:32)

The image shows a whiteboard with handwritten mathematical derivations. At the top, the magnitude of the derivative vector is given as $\|c'(t)\| = \sqrt{x'(t)^2 + y'(t)^2 + z'(t)^2} = ds$. Below this, it is shown that $c'(t) dt = \frac{c'(t)}{\|c'(t)\|} ds = T(t) ds$. The line integral of a vector field F over a curve C is then expressed as $\int_C F \cdot ds = \int_a^b F(c(t)) \cdot c'(t) dt = \int_a^b F(c(t)) \cdot T(t) ds$. A definition follows: $F \cdot T$ is the projection of F in the direction of the tangent vector to the curve. Finally, it concludes that the line integral of F over C is the integral of the tangential component of F with respect to the arc length.

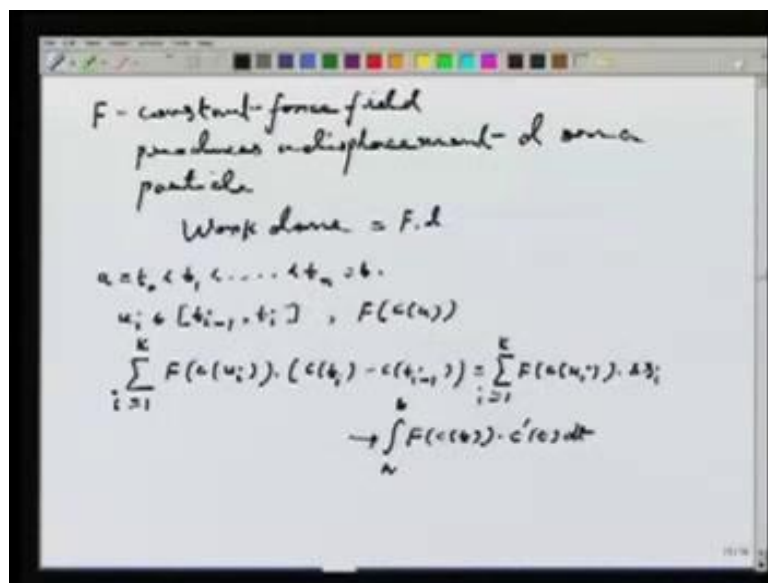

Because, I know that this is square root of x prime t square plus y prime t square plus z prime t square. This is the result which we have proved while talking about length of curves. We have done the thing only on \mathbb{R}^2 , but the analogous analysis can be done on \mathbb{R}^3 and you can show that the length of the curve is actually given by $\text{norm } c' dt$. So, all I am saying is that this formula we have seen and actually proved in two dimension, I am saying stating the same formula in three dimension.

So, I will write again what we have proved that this is $\text{norm } c' dt$, which is the element of arc length ds . So, this implies then that $c' dt$, if I look at that, that is $c' dt$ by $\text{norm } c' ds$ correct, how did I get this because, ds is $\text{norm } c' dt$. So, just formally look at it this way that dt equals to ds by $\text{norm } c'$, so $c' dt$ is c' by $\text{norm } c' ds$, this is just a formal way of saying this, but this then by my definition of the unit tangent vector is $T ds$.

Now, this has some implication, the implication is integral over C $F \cdot ds$, now can be written as integral a to b $F(c(t)) \cdot c'(t) dt$, which is our usual definition is same as integral a to b I am not changing $F(c(t))$ that stays dot, now $c'(t) dt$ I can write as $T ds$. So, but what is $F \cdot T$ what does this mean, it means actually the projection of the vector field F in the direction of the tangent vector to the curve, so this implies then. So, I will write it the meaning as the line integral now of F on C is the integral of the tangential component of F with respect to the arc length.

So, I will repeat again what I have shown is that integral of F over the curve c is integral a to b F of $c(t)$ dot $T(t)$ dt . Now, F dot t is the tangential component of the function in the direction of the tangent t on the curve c , so what I am doing is I am looking at the tangential component of the function this tangent is of course, drawn on the curve c that component is now getting integrated with the arc length of the curve, that is another meaning a geometrically related fact about the line. Because you can view the line integrals in this way also, it is interesting to observe that line integrals can actually be connected with the work done by a force field also that is what we are going to do now.

(Refer Slide Time: 45:28)

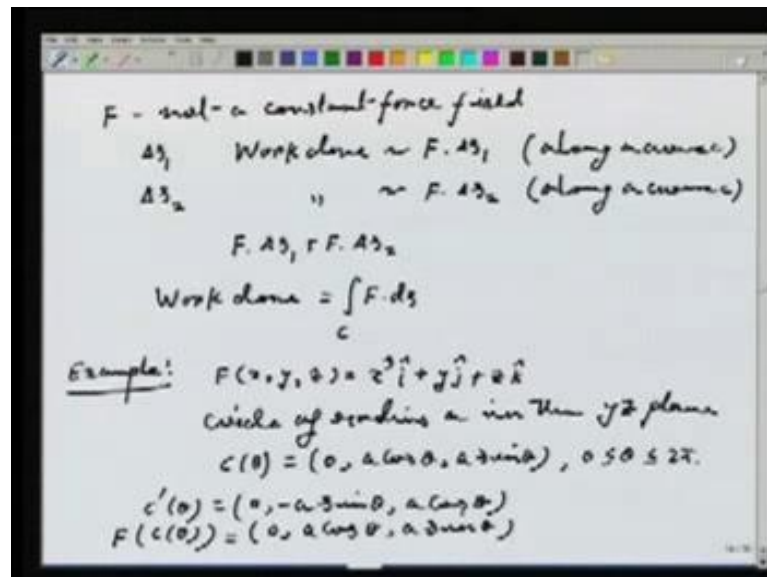

So, suppose F is a constant force field it acts on a particle and produces a displacement d on a particle, then we can actually calculate what is the work done, work done in this case is F dot d . Now, if f is not constant then you want to know how does one calculate the work done by this force field, this is where you are going to bring in the theory of line integrals. For that first I need an analog of the Riemann sums, which we have done in the one variable case, in this case the situation is as follows.

So, I take a partition of the parameter space a, b by t_0, t_1, \dots, t_n let us say, let us take some sample points u_i in the interval t_{i-1}, t_i and I look at the sample values that is F of $c(u_i)$, where f is a given force field. And then I can look at this Riemann sum summation i from 1 to k F of c of u_i times then the vector dot product $c(t_i) - c(t_{i-1})$, which is equals to summation i from 1 to k F of $c(u_i)$ dot product Δs_i . Now, it

can be shown that if I take finer and finer partitions, that is the norm of this partition going to 0; that means, the maximum length of this partition, which is the norm of a partition if that goes to 0.

One can show that this $\sum F \cdot \Delta s_i$ is actually better and better approximated by $\int_c F \cdot ds$ and this sum actually converges to the line integral, that is $\int_a^b F(c(t)) \cdot c'(t) dt$, it can be shown, but the proof of that is beyond the scope of this lecture. So, you are not going to prove it let us just assume this that this line integral can also be viewed as Riemann sums, the limits of the Riemann sums.

(Refer Slide Time: 48:34)

Now, using this let us go back to the question of work done again, suppose F is not a constant vector field in general, not a constant force field it acts on a particle and produces a displacement let us say Δs_1 . Then, the work done is approximately equal to $F \cdot \Delta s_1$, if in the subsequent time it produces a displacement of Δs_2 , then the work done is approximately equal to $F \cdot \Delta s_2$, so the total work done is $F \cdot \Delta s_1$ plus $F \cdot \Delta s_2$ and so on.

Now, this subsequent times which we are using is actually a partition of the parameter space and then using the Riemann sum one can actually prove that the total work done by a force field F , here we are displacing along a curve c let us say along a curve c , otherwise Δs_1 would not make sense along a given curve c . In that case the total work done using the theorem of Riemann sum turns out to be integral over c $F \cdot ds$.

Now, I have not given the proof of all this, but let us illustrate it by an example, so first I will give you a force field then a curve. Well the force field which I give is F of x, y, z equals to x cube i plus y j plus z k and the curve which I give is the circle of radius a in the $y z$ plane. So, then I can write down the equation of the curve also, so this is $c t$ since it is in the $y z$ plane, its first component is always 0, then $a \cos \theta, a \sin \theta$ 0 lesser equals to θ lesser equals to 2π .

So, the question I am asking is suppose I have a particle at the point 0 let us say and then I apply this force field, this particle moves around the whole circle comes back to 2π if that happens I will try to calculate what is the total work done. Well, what happens in this case well it is $c \theta$ first I have to calculate c prime θ that is 0 minus $a \sin \theta$ then $a \cos \theta$ and then I have to calculate what is F of $c t$. So, in this case it is F of $c \theta$ that is i ; obviously, get 0 here, then $a \cos \theta$ then $a \sin \theta$.

(Refer Slide Time: 52:30)

The image shows a whiteboard with handwritten mathematical work. At the top, it calculates the dot product of the force field F and the derivative of the curve $c'(\theta)$. The force field is $F(x, y, z) = (x^3, y, z)$ and the curve is $c(\theta) = (0, a \cos \theta, a \sin \theta)$. The derivative is $c'(\theta) = (0, -a \sin \theta, a \cos \theta)$. The dot product is calculated as $(0, a \cos \theta, a \sin \theta) \cdot (0, -a \sin \theta, a \cos \theta) = 0 - a^2 \sin \theta \cos \theta + a^2 \sin \theta \cos \theta = 0$. Below the calculation is a diagram of a circle in the yz -plane with radius a , centered at the origin. The x -axis is perpendicular to the plane of the circle. At the bottom, the line integral is shown as $\int_C F \cdot ds = \int_0^{2\pi} F(c(\theta)) \cdot c'(\theta) d\theta = 0$.

Then what is F of $c \theta$ dot c prime θ that is 0 $a \cos \theta, a \sin \theta$ dot 0 minus $a \sin \theta a \cos \theta$. If I do the dot product what I get is minus a square $\sin \theta \cos \theta$ plus a square $\sin \theta \cos \theta$, that is equals to 0, what does it mean, it means the force field is actually in the normal direction on the circle. So, if this is the circle in the y, z plane this is my x axis, then the force field is actually acting in the normal direction.

That means, it cannot move a particle along this curve; that means, the total work done by this force should be 0. That means, integral of F over c dot ds should be equals to 0,

but this by my definition is $\int_0^{2\pi} \mathbf{F}(c(\theta)) \cdot c'(\theta) d\theta$, but I have already calculated that $\mathbf{F}(c(\theta)) \cdot c'(\theta)$ is actually equal to 0, so this is equal to 0, so it matches with the physical observation, so now, let us sum up what we have learnt about line integrals.

First we have defined line integration of a vector field over a curve c of course, under certain conditions on the vector field and the conditions on the curve, the condition on the vector field is that it should be continuous; the condition on the curve is that c should be a differentiable function.

Next, we have shown that there exist an analog of the second fundamental theorem of calculus, when the vector field in the question is gradient of a scalar valued function. In that case many line integrals can be easily computed and we have given one such example. Then we have noted some elementary properties about line integrals one of them being, that if I reparametrize the curve, then the line integral does not change.

Then, we had a geometric view point towards the line integral, where we have proved that if a vector field \mathbf{F} is given, then its line integral over a curve c is nothing but, the integral of the tangential component of the function with respect to the arc length. And then comes the last topic, we have shown that line integral actually represents physically speaking, the work done by the force field \mathbf{F} in displacing a particle over a given curve c , in the next lecture we will start with surfaces and integrals of function over given surfaces.
