Module 2

Application of Navier Stokes equation for finding out viscosity (Part 1)

Good morning you remember that we had derived equation of motion that is Navier Stokes Equations and we had given you a problem not we had given a we had given the problem and solved also right. We said that the Navier Stokes Equation so useful that in many cases they are used and used in the sense you see that there is a velocity term, there is a there is a viscosity term, so shear stress term all these when whenever it was required or it is required you can use them.

(Refer Slide Time: 1:23)

Problem 1:- If an incompressible fluid is flowing between two vertical coaxial cylinders, and the outer one is rotating with an angular velocity ω , determine the velocity for the tangential laminar flow.

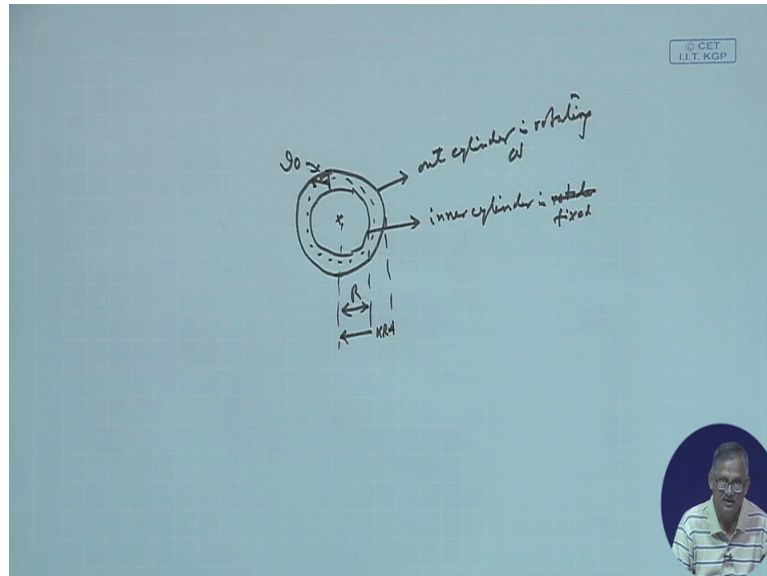

Solution: The flow is laminar and the fluid moves in a circular pattern.

Hence, from the physical understanding of the problem, the velocity components, $v_r = v_z = 0$, and $\partial v_\theta / \partial \theta = 0$

From Navier Stokes equation - $\rho v_\theta^2 / r = - \partial p / \partial r$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

And you remember we had solved the problem like this that cylinder two coaxial cylinders right two coaxial cylinders one is like that and another one is like this they were there and a fluid within this is there and we said that inner cylinder this is the inner cylinder is rotating no is fixed and the outer cylinder is rotating outer cylinder is rotating with an angular velocity of ω right and we said the velocity profile is like this v_θ right is the velocity profile. So for this we had done the solution right.

Now if the same problem if the same problem if we say in a different way in the problem remains explicitly same the language wise that if an incompressible fluid is flowing between two vertical coaxial cylinders, and the outer one is rotating with an angular velocity of ω , determine the velocity for the tangential laminar flow.

So there is no change in the language, no change in the problem only if we were asked now that you if you remember we have said that this was R and this was kR , right that was our problem given earlier.

(Refer Slide Time: 3:54)

Now if we do the same problem like this right if we do the same problem like this right where you see here instead of R at the boundary at the inner one and kR at the outer one if we just interchange that kR is in the inner one and R is in the outer one, right.

So we say now that we have these two coaxial cylinders right and the radii R like this this is kR and this is R , right all other remains same that velocity profile is like this v_θ right here we have seen that outer cylinder is rotating with an angular velocity of ω , inner cylinder is fixed right so the same problem which just changed the radii.

(Refer Slide Time: 5:50)

$$\begin{aligned} &= \omega k^2 R^2 / (1 - k^2)r - \omega k^2 r / (1 - k^2) \\ &= (\omega k^2 R^2 - \omega k^2 r^2) / (1 - k^2)r \\ &= \omega k^2 [R^2 - r^2 / (1 - k^2)r] \end{aligned}$$

Then if you remember what was our earlier solution that let me show you first our earlier solution was like this v_{θ} was ωk^2 into R^2 minus r^2 divided by $1 - k^2$ into r , this was our earlier solution that is under this situation, this was our solution, right.

Now we have changed we have said only all other things remains same only we are changing the radii inner radii and outer radii, so we made inner radii kr and outer radii R , right. In this case outer radii was multiple of k which is more than 1, in this case inner radii is a multiple of kR rather which is less than 1, right because here in this case as it is appearing R is greater than kR in this case it is appearing R is less than kR . So it is multiple of kR where the constant is greater than 1 or rather in this case it is less than 1, right all other things remains same.

(Refer Slide Time: 7:34)

Problem 1:- If an incompressible fluid is flowing between two vertical coaxial cylinders, and the outer one is rotating with an angular velocity ω , determine the velocity for the tangential laminar flow.

Solution: The flow is laminar and the fluid moves in a circular pattern.

Hence, from the physical understanding of the problem, the velocity components, $v_r = v_z = 0$, and $\partial v_\theta / \partial \theta = 0$

From Navier Stokes equation $-\rho v_\theta^2 / r = -\partial p / \partial r$

$$0 = \frac{\partial}{\partial r} \left(\frac{1}{r} \frac{\partial}{\partial r} (r v_\theta) \right)$$

and $0 = -\partial p / \partial z + \rho g_z$

from the eqⁿ, $\frac{\partial}{\partial r} \left(\frac{1}{r} \frac{\partial}{\partial r} (r v_\theta) \right) = 0$

or, $\frac{1}{r} \frac{\partial}{\partial r} (r v_\theta) = A$

or, $\frac{\partial}{\partial r} (r v_\theta) = A r$

or, $r v_\theta = A r^2 / 2 + B$

or, $v_\theta = A r / 2 + B / r$

Applying B.C., $v_\theta = 0$, at $r = R$ and $v_\theta = \omega k R$ at $r = k R$

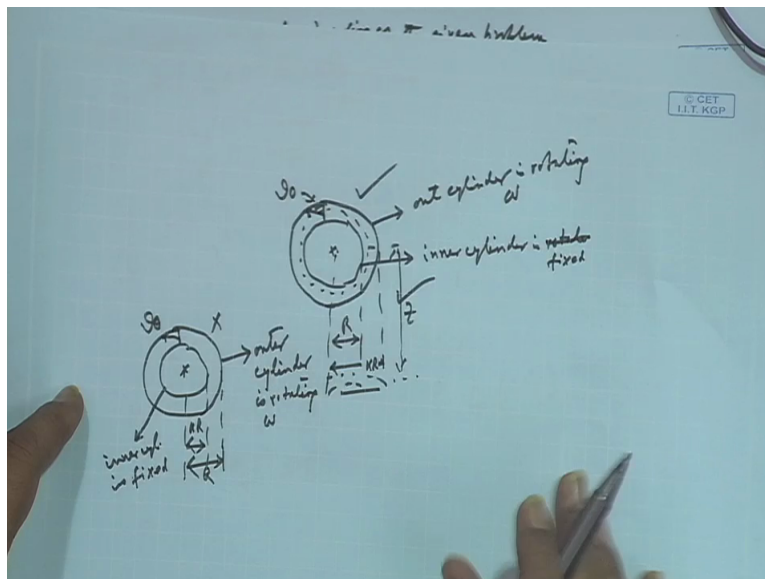

$$\therefore 0 = A R / 2 + B / R$$

$$\text{and } \omega k R = A k R / 2 + B / k R$$

If this be the case then let us see how we can proceed right, you see we have studied here with that from the given problem v_r is equals to v_z is equals to 0, $\partial v_\theta / \partial \theta$ is 0 same.

From Navier Stokes Equation we got the first equation $\rho v_\theta^2 / r$ is equals to $-\partial p / \partial r$ minus $\rho v_\theta^2 / r$ is equals to $-\partial p / \partial r$ this was (7:55) from the first equation, from the second equation we got 0 is equals to $\frac{\partial}{\partial r} \left(\frac{1}{r} \frac{\partial}{\partial r} (r v_\theta) \right)$, this was from the second equation. And from the third equation we got 0 is equals to $-\partial p / \partial z + \rho g_z$.

(Refer Slide Time: 8:23)

from the physical understanding of the given problem

$$v_r = v_z = 0 \quad \& \quad \frac{\partial v_\theta}{\partial \theta} = 0$$

steady, laminar, incompressible fluid.

- ① $-\rho \nu \theta'' = -\frac{\partial p}{\partial r}$
- ② $0 = \frac{\partial}{\partial r} \left(\frac{1}{r} \left(\frac{\partial}{\partial r} (r v_\theta) \right) \right)$
- ③ $0 = -\frac{\partial p}{\partial z} + \rho g_z$

$$0 = \frac{\partial}{\partial r} \left(\frac{1}{r} \left(\frac{\partial}{\partial r} (r v_\theta) \right) \right)$$

$$A = \frac{1}{r} \left(\frac{\partial}{\partial r} (r v_\theta) \right); \quad \omega, \quad A r = \frac{\partial}{\partial r} (r v_\theta)$$

$$r v_\theta = \frac{A r^2}{2} + B$$

B.C. ① $v_\theta = 0$ at $r = KR$; ② $v_\theta = \omega R$ at $r = R$

- ① $-\rho \nu \theta'' = -\frac{\partial p}{\partial r}$
- ② $0 = \frac{\partial}{\partial r} \left(\frac{1}{r} \left(\frac{\partial}{\partial r} (r v_\theta) \right) \right)$
- ③ $0 = -\frac{\partial p}{\partial z} + \rho g_z$

$$0 = \frac{\partial}{\partial r} \left(\frac{1}{r} \left(\frac{\partial}{\partial r} (r v_\theta) \right) \right)$$

$$A = \frac{1}{r} \left(\frac{\partial}{\partial r} (r v_\theta) \right); \quad \omega, \quad A r = \frac{\partial}{\partial r} (r v_\theta)$$

$$r v_\theta = \frac{A r^2}{2} + B$$

B.C. ① $v_\theta = 0$ at $r = KR$; ② $v_\theta = \omega R$ at $r = R$

$$0 = \frac{A(KR)^2}{2} + B \quad \dots \quad \text{①} \quad \text{②} - \text{①}$$

$$R \omega = \frac{A R^2}{2} + B \quad \dots \quad \text{③} \quad R^2 \omega = \frac{A}{2} (R^2 - K^2 R^2)$$

$$R \omega = \frac{A R^2}{2} + B \quad \dots \quad \text{④} \quad R^2 \omega = \frac{A R^2}{2} (1 - K^2)$$

So all these three equations remain identical so we can write from the physical understanding of the given problem we can write v_r is equals to v_z is equals to 0 and $\frac{d}{d\theta} v_\theta$ is equals to 0, it is a steady, laminar and incompressible fluid right this was all given. So this two remain same so then from the Navier Stokes Equations we can write number 1 equation minus ρv_θ^2 by r is equals to minus of $\frac{dP}{dr}$ right, than we also can write that second equation we can write 0 is equal to $\frac{d}{dr} \left(\frac{1}{r} \frac{d}{dr} (r v_\theta) \right)$, right (2, 3) right.

And third one from the Navier Stokes Equations we can write 0 is equals to minus $\frac{dP}{dz}$ plus ρg_z right. So obviously that this is R and this is θ and z will be this right z will be this one is there, another is this so this is the z , right the same is here true, ok. If that be true than here we have one unknown v_θ because we have been asked what is the velocity right so that tangential velocity if we want to find out that is v_θ than this solution is good enough 0 is equals to we can take $\frac{d}{dr} \left(\frac{1}{r} \frac{d}{dr} (r v_\theta) \right)$ because here v_θ is there, here also v_θ is there, but here atleast the equation is much from here also we can solve, from here it is difficult because obviously you will take the one where your solution is feasible.

So if we take this $\frac{d}{dr} \left(\frac{1}{r} \frac{d}{dr} (r v_\theta) \right)$, right if we take this as solving equation then on first integration as we found out earlier 0 is equals to or this was ok constant integral constant let us write here A is equals to $\frac{1}{r} \frac{d}{dr} (r v_\theta)$, right this was on first integration so which we could write on simplification as Ar is equals to $\frac{d}{dr} (r v_\theta)$, right right.

So on second integration we can write than $r v_\theta$ is equals to $\frac{Ar^2}{2} + B$ right $\frac{Ar^2}{2} + B$, upto this the solution is exactly identical. Now where the change from the two problems that is again I am showing that this was already solved problem and this is the problem which we r now handling, right.

So here it was rotating if it is constant here also it is rotating this is constant, here the outer radius was kr , inner radius was R , here outer radius is R and inner radius is kr , this is the difference, right. So upto this we have the same solution now when we apply the boundary condition the boundary condition is what first boundary condition we can write boundary condition one is that here right.

So this is constant and this is rotating. So this v_θ is equals to 0 at r is equals to kR right, this is boundary one and boundary condition two we can write v_θ is equals to ωR

right at r is equals to capital R , right so ωR at r is equals to capital R . So if that be true by applying the first boundary v theta is equals to 0 at r is equals to kR right, we have this two one A and B , ok this was A and this is B .

Now if we put first boundary here that r is equals to kR v theta is equals to 0 that means this is 0 0 is equals to $A r^2$ by 2 or in this case r is equals to 0 so this also becomes 0 then B becomes equals to 0 at r v theta is equals to 0 r is equals to kR sorry sorry v theta is equals to 0 at r is equals to kR . So v theta is 0 so this becomes 0 at r is equals to kR .

So this is becoming $A K^2 R^2$ by 2 plus B this is say equation number 1, right and the second equation is v theta is equals to ωR at r is equals to capital R . So instead of instead of this we write v theta is equals to ωR at r is equals to capital R . So second one we can write R^2 right ω or ωR^2 is equals to A into R^2 divided by 2 plus B right.

So from these two equations by solving we can say that B becomes equals to 0 right so if we if we subtract this 2 minus 1, if we do 2 minus 1 then B becomes equals to 0, then $R^2 \omega$ this is equals to A by 2 if we take common then it becomes R^2 into R^2 minus $k^2 R^2$, or if we take R^2 common then ω is equals to or $R^2 \omega$ is equals to $A R^2$ by 2 $1 - k^2$, right.

(Refer Slide Time: 17:55)

The image shows a whiteboard with handwritten mathematical equations. At the top, it says $R^2 \omega = \frac{AR^2}{2} (1 - k^2)$ and $B = 0$. Below that, it says $w, A = \frac{2W}{(1 - k^2)}$. Then, $r \theta_0 = \frac{Ar^2}{2} + B$ with a circled A . Next, $r \theta_0 = \frac{2WR^2}{2(1 - k^2)} + 0$. Finally, $w, \theta_0 = 2 \frac{WR^2}{1 - k^2} = \left(\frac{W}{1 - k^2} \right) r$.

So from there we can also write this is that ok let us write here once again $R^2 \omega$ is equals to $A R^2$ by 2 into $1 - k^2$ or A is equals to this R^2 goes out so 2 ω over $1 - k^2$ right. So we had B is equals to 0 and we had the original

So let us substitute here v_{θ} is equals to 0 at r is equals to kR , this is one and v_{θ} is equals to let us let us take it to that site and v_{θ} is equals to second ωR at r is equals to R , not ωkR , ωR at r is equals to R , right. So if that be true than by putting the first boundary that is v_{θ} is equals to 0 at r is equals to kR , we can write this was $r v_{\theta}$ $A r$ square by 2 plus B that was our integration, right.

So we write here that in this case we do not need this right so we can write then that (()) (21:42) v_{θ} is 0 at r is equals to kR , and v_{θ} is equals to ωR at r is equals to R . So if we put this boundary that is v_{θ} is 0 at r is equals to kR , so v_{θ} is equals to 0 at r is equals to kR , then we get here this is kR square right kR square. (())(22:21) we can we can write it here if we have that thing ok, it will be 2 square, right and obviously this will bring down to normal ok kR square this also has to come to normal only so this is (())(23:00) is out.

So kR square by 2 and this was B plus B only right plus B only right. Boundary condition first one if we have put here so this is 0 right and then this r is equals to kR is kR square and no no no no no let us let us let us skip let us skip that thing this one v_{θ} then then only because we cannot put r_0 so it is $A r$ by 2 plus $B r$ here we have to apply exactly here we have to apply that v_{θ} is equals to ωR at r is equals to R .

So from the first boundary v_{θ} is equals to 0, at r is equals to kR , if we put that it is equals to 0 so here it is kR square, here it is then kR square, ok so it is kR square by 2, right plus here it is $(k) B$ by kR , right because r we have first v_{θ} is equals to 0 at r is equals to kR , so (())(25:02) plus B by kR and the second one was boundary condition was v_{θ} is equals to ωR at r is equals to R , so v_{θ} is ωR at r is equals to R . So in that case this will be $A R$ by 2 plus this is B by R , right.

(Refer Slide Time: 25:51)

$$0 = \frac{A(kR)^2}{2} + \frac{B}{kR} \quad \therefore B = -\frac{A(kR)^2}{2(kR)}$$

$$\omega R = \frac{AR}{2} + \frac{B}{R} \quad \checkmark$$

$$\omega R = \frac{AR}{2} + \left(-\frac{A(kR)^2}{kR(2kR)} \right)$$

$$= A \left[\frac{R}{2} - \frac{k^2 R^2}{kR(2kR)} \right] = A \left[\frac{R}{2} - \frac{1}{2} \right] = A \left[\frac{1}{2} \right]$$

$$\therefore A = \frac{\omega R}{\frac{1}{2}} = 2\omega R$$

$$A = \frac{W}{\left(\frac{2R-2}{2R} \right)} = \frac{2WR}{2(R-1)} = \frac{WR}{(R-1)}$$

$$\therefore \omega R = \frac{AR}{2} + \frac{B}{R} = \frac{WR^2}{2(R-1)} + \frac{B}{R}$$

$$\omega R = \frac{AR}{2} + \frac{B}{R} \quad \checkmark$$

$$\omega R = \frac{AR}{2} + \left(-\frac{A(kR)^2}{kR(2kR)} \right)$$

$$= A \left[\frac{R}{2} - \frac{k^2 R^2}{kR(2kR)} \right] = A \left[\frac{R}{2} - \frac{1}{2} \right] = A \left[\frac{1}{2} \right]$$

$$\therefore A = \frac{\omega R}{\frac{1}{2}} = 2\omega R$$

$$A = \frac{W}{\left(\frac{2R-2}{2R} \right)} = \frac{2WR}{2(R-1)} = \frac{WR}{(R-1)}$$

$$\therefore \omega R = \frac{AR}{2} + \frac{B}{R} = \frac{WR^2}{2(R-1)} + \frac{B}{R}$$

$$\frac{B}{R} = \omega R - \frac{WR^2}{2(R-1)} = WR \left[1 - \frac{1}{2(R-1)} \right]$$

$$\therefore B = WR \left[1 - \frac{1}{2(R-1)} \right] \quad \checkmark$$

So that which we did a little here something difficult here now let us rewrite here so we have 0 is equals to AkR square by 2 plus B by kR and we also have omega R is equals to AR by 2 plus B by R right. So if we if we take instead of B so B is equals to from here we can write B is equals to minus AkR whole square by 2 right divided by kR so this is kR minus AkR square by 2 by 2 kR that is B if we take this equation and if we substitute here then omega R is equals to AR by 2 plus B is minus minus A kR square by 2 kR right 2 kR and we also have 1 kR here right.

So on simplification we can write that this is equals to if A is common R by 2 minus k square R square divided by kR into 2kR, right. So this kR kR this k square R square k square R square goes out then this becomes R by 2 minus half right. So this is equals to into A of

course right. So ωR is there therefore A is equals to ωR of course this we can further simplify as if we take R common right 1 by 2 minus 1 by $2R$, right from there if we take out this R if we write again ωR is equals to AR into 1 by 2 minus 1 by $2R$, right.

So this R goes out, so A is equals to ω by $2R$ and here it is $2R$ minus 2 right is equals to $2\omega R$ divided by $2R$ minus 1 , so this goes out this ωR by R minus 1 , so if it is A then B can be written as form here we can write that ωR is equals to AR by 2 plus B by R from there we can write substituting A ωR square by 2 into R minus 1 plus B by R , right.

So from there if we if we take this ωR so B by R is equals to B by R is equal to ωR minus ωR square by $2R$ minus 1 , so if we take ωR common than 1 minus 1 by $2R$ minus 1 , right so B is equals to ωR square into 1 minus 1 by $2R$ minus 1 , right. So we know A , we know B .

(Refer Slide Time: 30:43)

The screenshot shows a PowerPoint slide with the following content:

$$v_{\theta} = \omega R \frac{(kR/r - r/kR)}{(k - 1/k)}$$

$$\text{Shear stress } \tau_{r0} = -\mu \left[r \left(\frac{\partial v_{\theta}}{\partial r} \right) / \partial r + 1/r \left(\frac{\partial v_{\theta}}{\partial \theta} \right) \right]$$

$$= -2\mu \omega R^2 (1/r^2) (k^2 / (1 - k^2))$$

Logos for IIT KHARAGPUR and NPTEL ONLINE CERTIFICATION COURSES are visible at the bottom of the slide.

$$v_\theta = \omega R \frac{(kR/r - r/kR)}{(k - 1/k)}$$

Shear stress $\tau_{r\theta} = -\mu[r(\partial(v_\theta/r) / \partial r) + 1/r (\partial v_r / \partial \theta)]$

$$= -2\mu \omega R^2 (1/r^2)(k^2/(1-k^2))$$

Then we can substitute and by doing that we get this ok we get this this is the solution ok v theta is omega R into kR by R to R minus kR by k minus 1 by k and and and of course in all the cases we have we we have missed that one k yes we have missed that one k in this cases. So this is the ultimate solution which we get that v theta is equals to omega R into kR by r r by kR by k minus 1 by k and shear stress ((31:28) theta is minus mu r del v theta del r del v theta by r del del r v theta by r plus 1 by r del vr del theta. So that is minus mu 2 omega square into 1 minus r square into k square by 1 minus k square. So you do the changes in the slide accordingly and converting into this, ok thank you.
