

Course on Momentum Transfer in Process Engineering
By Professor Tridib Kumar Goswami
Department of Agricultural & Food Engineering
Indian Institute of Technology, Kharagpur
Lecture 18
Module 4
Flow through flat and parallel plates

Okay if we remember that in the previous class we had given a problem and we asked that you try and if you cannot do this then we will do that in this class so let us see whether you are able to solve that or not, okay.

(Refer Slide Time: 0:57)

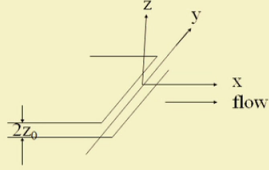

Problem: A fluid of constant density is flowing in laminar flow at steady state in the horizontal x direction between two flat and parallel plates, the distance between the two plates in the vertical z direction is $2z_0$. Using shell momentum balance, drive the equation for the profile within this fluid.

The slide also features the IIT Kharagpur logo on the left and the NPTEL Online Certification Courses logo on the right, with a small circular portrait of Professor Tridib Kumar Goswami in the bottom right corner.

So yeah this was the problem which we had given you that A fluid of constant density is flowing in laminar flow at steady state in the horizontal x direction and between two flat and parallel plates, the distance between the two plates in the vertical z direction is said $2z_0$. Using shell momentum balance, derive the equation for the profile within this fluid, right?

So that means say a fluid of constant density is flowing in laminar flow at steady state in the horizontal x direction, so if we have the plates like this if we have the plates like this, right? 2 plates like this if we have, then these two plates, right? One over the other these two plates the fluid is flowing within this and we have to find out the profile, right? Derive the equation for the profile within this fluid, this we have to get it.

(Refer Slide Time: 2:18)

- Steady laminar flow $\rightarrow v_y = v_z = 0$; and $\partial v_x / \partial x = 0$; $g_x = 0$

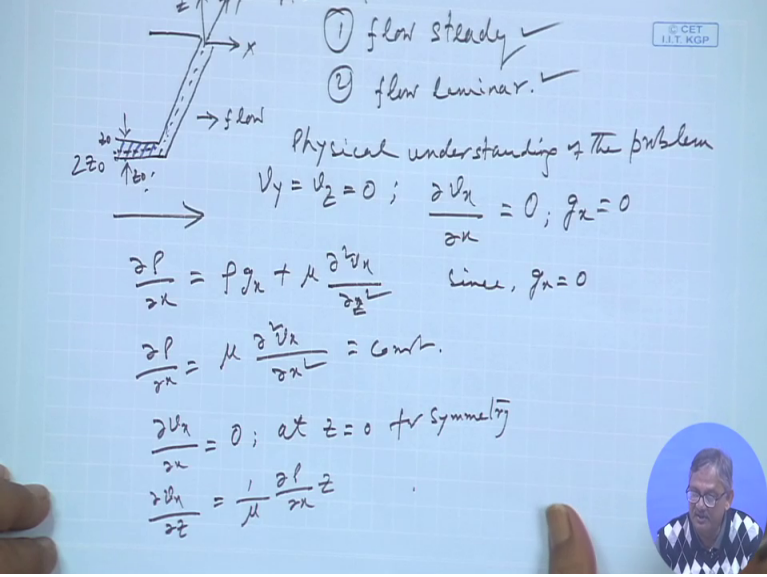

$$\frac{\partial p}{\partial x} - \rho g_x = \mu \frac{\partial^2 v_x}{\partial z^2}$$

$$\text{since } g_x = 0; \quad \frac{\partial p}{\partial x} = \mu \frac{\partial^2 v_x}{\partial z^2}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now this if we (plo) if we if we draw if we draw this that as we showed you one one paper like this, right?

(Refer Slide Time: 2:43)

① flow steady ✓
② flow laminar. ✓

Physical understanding of the problem
 $v_y = v_z = 0$; $\frac{\partial v_x}{\partial x} = 0$; $g_x = 0$

$$\frac{\partial p}{\partial x} = \rho g_x + \mu \frac{\partial^2 v_x}{\partial z^2} \quad \text{since } g_x = 0$$

$$\frac{\partial p}{\partial x} = \mu \frac{\partial^2 v_x}{\partial z^2} = \text{const.}$$

$\frac{\partial v_x}{\partial z} = 0$; at $z = 0$ for symmetry

$$\frac{\partial v_x}{\partial z} = \frac{1}{\mu} \frac{\partial p}{\partial x} z$$

© CET I.I.T. KGP

And the other one as say like this okay and if we have the say this is y direction this is x direction and this is z direction, right? So x, y and z and the flow is taking place like this the flow is taking place like this the distance between these two plates are say $2z_0$, so this was our problem which we had asked to solve. So it is flowing along like this, right? Between these two plates between these two plates, now these two plates as small as we can think of. That means it will two plates

we there is there are the two plates and say one over other like this and the fluid is flowing below this in this direction so this we had taken x as this y as this direction and z is the gap between the two, right?

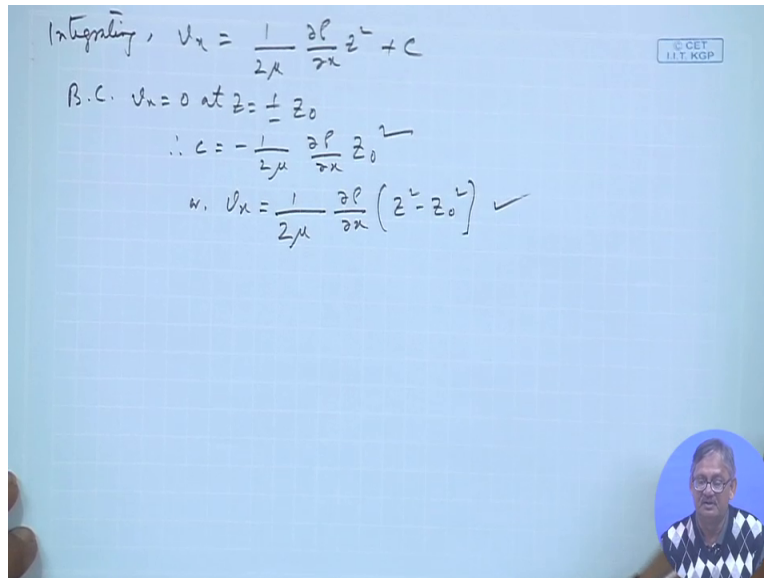

So if we take this kind of solution, then we assume here again number 1, the flow is steady, number 2, the flow is laminar, right? So this assumption we make that flow is steady flow is laminar if that be true, then from the physical understanding of the problem so from the physical understanding of the problem we can then say that v_y is equals to v_z is equals to 0 because flow is taking only in the x direction, right? So there is no flow in the y direction, there is no flow in the vertical z direction.

If that be true if there is no flow in the vertical y and z direction horizontal this and vertical z direction only in the x direction because it is steady because it is laminar, right? So if that be true, then v_y is equal to v_z is equals to 0 and there is no $\frac{d v_x}{d x}$ present, that is $\frac{d v_x}{d x}$ is equals to 0 and we simply for all practical purposes say that g_x is equals to 0 because that is in the x direction is the flow. So g_x also we can assume to be equals to 0, so we can write $\frac{\Delta P}{\Delta x}$ that is is equals to ρg_x plus $\mu \frac{d^2 v_x}{d x^2}$, right?

And since g_x is equals to 0 we can write $\frac{\Delta P}{\Delta x}$ is equals to $\mu \frac{d^2 v_x}{d x^2}$, right? Because g_x we have assumed to be equals to 0, right? And we said in the beginning that this distance as small as we can think if that be true then also then also no is a proper definition of the physical problem is there that this distance is as small as we can think of, right? If being very small is $2 z_0$ we can say that it is so. So then we can say $\frac{\Delta P}{\Delta x}$ is $\mu \frac{d^2 v_x}{d x^2}$ square which is nothing but a constant, right?

So we can we can now integrate it and say $\frac{d v_x}{d x}$ this is equals to 0, right? Because $\frac{\Delta P}{\Delta x}$ is constant so $\frac{d v_x}{d x}$ is equals to 0 and this is true at z is equals to 0 for the symmetry $\frac{d v_x}{d x}$ is 0 at z is equals to 0 because this is $2 z_0$ so 1 you can tell that it is $1 z_0$ and another is another z_0 from the center, right? So this we can that 1 is z_0 and the other is another z_0 from the symmetry, so $\frac{d v_x}{d x}$ is equals to 0 at z is equals to 0, right? So then we can also write $\frac{d v_x}{d z}$ it was $\frac{d v}{d z} = 2 v_x \frac{d z}{d x}$ square, right? $\frac{d^2 v_x}{d z^2}$ square, then $\frac{d v_x}{d z}$ this is equals to 1 by $\mu \frac{\Delta P}{\Delta x}$ into z , right?

(Refer Slide Time: 9:57)

Integrating, $v_x = \frac{1}{2\mu} \frac{\partial p}{\partial x} z^2 + C$

B.C. $v_x = 0$ at $z = \pm z_0$

$\therefore C = -\frac{1}{2\mu} \frac{\partial p}{\partial x} z_0^2$

w. $v_x = \frac{1}{2\mu} \frac{\partial p}{\partial x} (z^2 - z_0^2) \checkmark$

So on integration we can say on integration we can say that v_x is equals to $\frac{1}{2\mu} \frac{\partial p}{\partial x} z^2 + C$ that is constant. So we can now put the boundary condition that is v_x is equals to 0 at z is equals to plus minus z_0 , right? So you can write C is equals to minus $\frac{1}{2\mu} \frac{\partial p}{\partial x} z_0^2$ or you can say v_x is equals to $\frac{1}{2\mu} \frac{\partial p}{\partial x} (z^2 - z_0^2)$, right?

So this way we can easily find out some or other problem which we come across and say this is the velocity profile for $v_x = \frac{1}{2\mu} \frac{\partial p}{\partial x} (z^2 - z_0^2)$, right? Then now let us move to some other situation other situation in the sense other come problem, in this manner we have problem now we let us say let us say a vertical or horizontal calandria, you know calandria? Calandria is normally said for heat transfer where evaporators or (())(11:59) they are being concentrated, right?

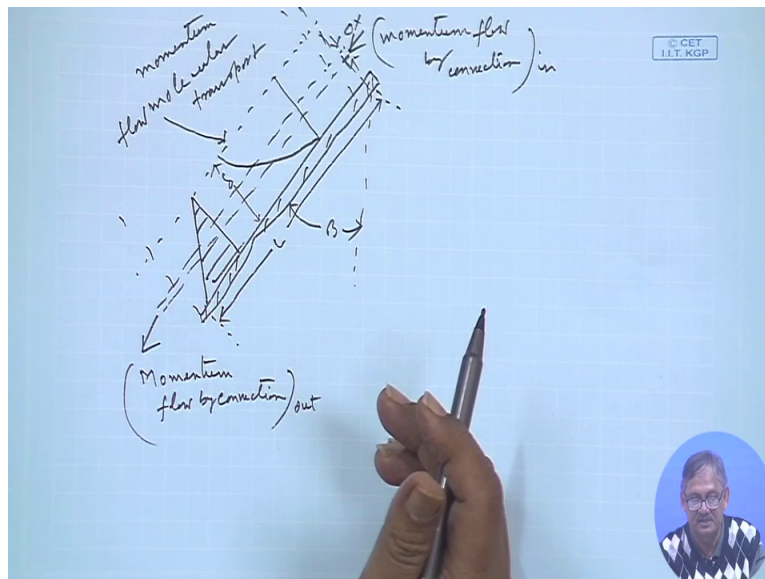

So you you have a concentration of one say food material or a chemical solution whatever, so one solution you have which has one concentration and you want to concentrate it to another concentrated one, right? So say for 60 percent to 80 percent you want to concentrate or 60 percent to 90 percent you want to concentrate in a in a film. So what you will do, you will you will fall this a one side say say if you take this as a heat exchanger so one side you will make this like this one is the film which is follow and another side is your heating medium.

So if that be done that one side is film and another side is the heating medium, then while this fluid is falling from here to here when this fluid is falling from here to here that time by the time

it falls from there to there it will get concentrated, right? Now, for that as far as heat transfer is concerned you have to consider heat transfer, but for the flow of the fluid how the fluid will behave what is the velocity profile what is the stress profile shear stress profile that if we want to know then you have to consider it right from the beginning it may be a vertical film or vertical vault or vertical heating medium or it can be a inclined one.

So depending on or which can be made depending on the inclination angle it can be made vertical or horizontal, right? So let us now talk about that it may take it may not be possible to complete in one class, but okay if require we can carry over to the next class, right?

(Refer Slide Time: 14:35)

So let us now take here one such situation say we have one film we we have one solid heating surface or solid heating surface like this on which a film is there. Now this film we are assuming it to be a little assuming it to be a little expanded or in a in a microscopic view or enlarge view rather if we look into an enlarged view, then so if take a volume element here also we will do the mass balance or momentum balance rather that momentum balance on the on the volume element this volume element what we are looking into that we have here say x , y and z three coordinates if we are talking about, right?

And if this is the length, right? And if we say that okay from here from here, right? So this is the end effect without the end effect we have so you remember earlier we had said the end effect, right? We take the liquid where there is no end effect, right? And fluid is flowing this way and

we do the momentum balance, right? So here momentum flow flow by convection this is out, similarly momentum flow by convection this is in, right?

So in minus out is like that and (moli) momentum flow by molecular transport so momentum flow by molecular transport that we can say this is working here, okay on the on the on the on the fluid, right? Okay and say afterwards when we will look at momentum flux distribution how it is, it will look this, right? It will look like this momentum flux distribution and if we look how the velocity would like so it will look like this this is the solid surface this is the open surface that this is the film this is the film which is there or this is the film which is there, right?

So this film is moving from this angle, right? Let the angle be beta let the angle be beta like this, right? So so we can do and this length we have said and okay now the the volume element which we are taking is this as Δx , right? And this we have taken and if the thickness of the thickness of the film is Δ thickness of the film is Δ , right? So we have Δx as 1 and the other one Δ other one is taken as L and third one may be w , right? So in this then some assumptions and some assumptions are there which we must know.

(Refer Slide Time: 20:11)

<https://www.google.co.in/search?q=falling+film+evaporator&oq=Falling+film&aqs=chrome.0.0j69i57j0l4.5767j0j8&sourceid=chrome&ie=UTF-8>

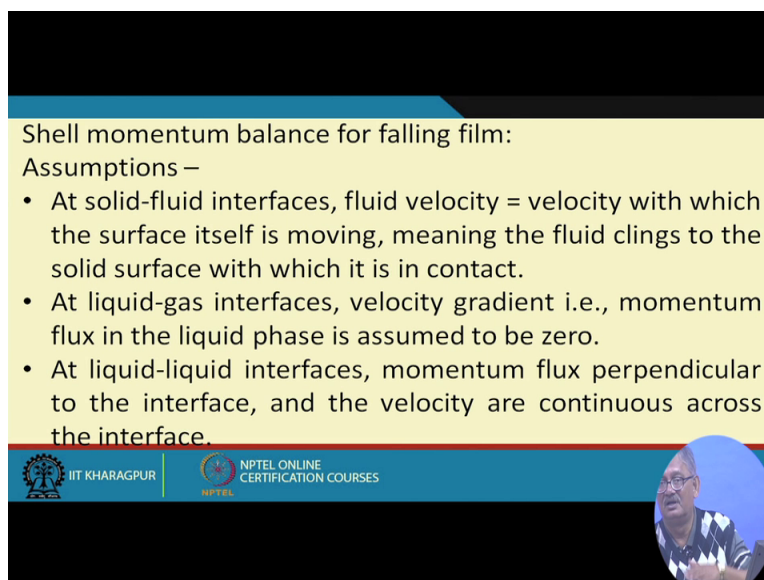

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So this is a typical typical such kind of thing actual you see that fluid is flowing this is absolutely of course vertical, so a film is falling here and this film by that time it comes to the other end is getting evaporated and getting concentrated, right? So one is heating medium and other is the

film which is to be concentrated, right? So from this this type of things are called calandria and through which we are getting things evaporated, okay.

Now we will do the shell momentum balance and for that we need the assumptions to be also kept in mind. Now these assumptions obviously are very very (perti) pertinent such that we can we we can actually visualize the problem described. Now the problem described is that we have a vertical plane we have a vertical heating medium and this is inclined the inclination is angle beta and we have taken a volume element where it is delta x is the thickness, right? Of the film which we are doing the shell momentum balance that shell thickness is delta x, right? We have shown that the length is L and and the other third z direction that can be as maybe w or width or whatever corresponding, right?

(Refer Slide Time: 22:01)

Shell momentum balance for falling film:
Assumptions –

- At solid-fluid interfaces, fluid velocity = velocity with which the surface itself is moving, meaning the fluid clings to the solid surface with which it is in contact.
- At liquid-gas interfaces, velocity gradient i.e., momentum flux in the liquid phase is assumed to be zero.
- At liquid-liquid interfaces, momentum flux perpendicular to the interface, and the velocity are continuous across the interface.

The slide also features logos for IIT KHARAGPUR and NPTEL ONLINE CERTIFICATION COURSES, and a small circular inset image of a man speaking.

So we need certain assumptions to be kept in mind and those assumptions are like this that a solid fluid interface and fluid velocity is at the solid fluid interface fluid velocity is the velocity with which the surface itself is moving, right? This we have said earlier also that the surface on which the fluid is moving if the surface is the surface is stick or surface is fixed, then this fluid surface is also sticking or clinging to the surface of the solid, so that solid fluid interface this fluid is clinging and this is called that it is attaining the velocity of the solid since the solid is not moving so we can say that the fluid is clinging to the solid and that is what we have assumed first, right?

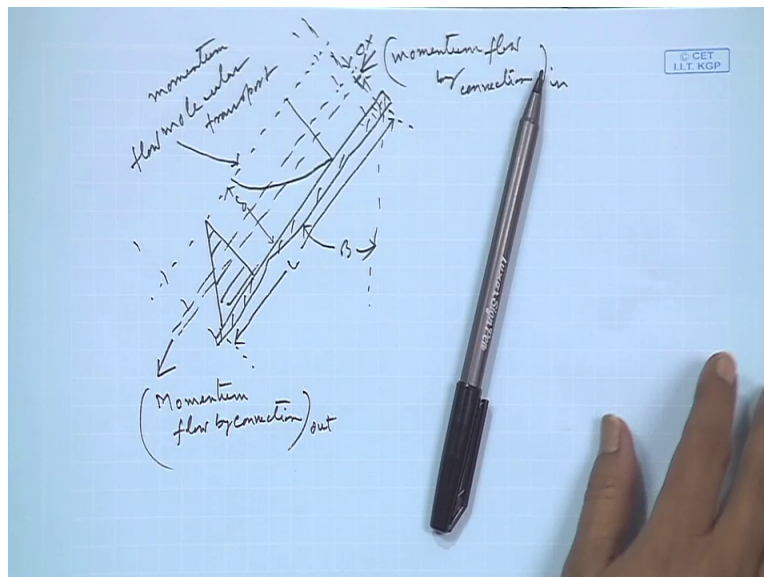

(Refer Slide Time: 23:09)

Shell momentum balance for falling film:
Assumptions –

- At solid-fluid interfaces, fluid velocity = velocity with which the surface itself is moving, meaning the fluid clings to the solid surface with which it is in contact.
- At liquid-gas interfaces, velocity gradient i.e., momentum flux in the liquid phase is assumed to be zero.
- At liquid-liquid interfaces, momentum flux perpendicular to the interface, and the velocity are continuous across the interface.

IIT KHARAGPUR NPTEL ONLINE CERTIFICATION COURSES 14

(Refer Slide Time: 23:15)

Then at liquid gas interface, now liquid gas interface is this one, right? Liquid gas interface is this one this is the liquid and above which is the gas this is the solid we said, right? This is the fluid or liquid which is getting getting heated or or concentrated.

(Refer Slide Time: 23:33)

Shell momentum balance for falling film:
Assumptions –

- At solid-fluid interfaces, fluid velocity = velocity with which the surface itself is moving, meaning the fluid clings to the solid surface with which it is in contact.
- At liquid-gas interfaces, velocity gradient i.e., momentum flux in the liquid phase is assumed to be zero.
- At liquid-liquid interfaces, momentum flux perpendicular to the interface, and the velocity are continuous across the interface.

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

So at liquid gas interface velocity gradient that is the momentum flux in the liquid phase is assumed to be 0 at this point the velocity the velocity gradient at this point that is momentum flux in this phase is liquid phase is assumed to be 0. And at the liquid liquid interface momentum flux perpendicular to the interface and the velocity are continuous across the interface. So these three assumptions we are we are setting in the beginning so that subsequently when we will do the analysis that time we have no problem.

So I I repeat the assumptions once more that for the shell momentum balance for falling film we assume at solid fluid interface fluid velocity is the velocity with which the surface itself is moving this means the fluid clings to the surface solid surface with which it is in contact. At liquid gas interface velocity gradient that is momentum flux in the liquid phase is assumed to be 0 and at liquid liquid interfaces momentum flux perpendicular to the interface and the velocity are continuous across the interface, right?

(Refer Slide Time: 25:36)

Rate of momentum in - Rate of momentum out
+ Sum of the forces = Rate of momentum accumulation.

Rate of z momentum in by convection = $W \Delta x v_z (\rho v_z) |_{z=0}$
 Rate of z momentum out by convection = $W \Delta x v_z (\rho v_z) |_{z=L}$
 Rate of momentum in by molecular transport
 = $L W \tau_{xz} |_{x}$
 Rate of momentum out by molecular transport
 = $L W \tau_{xz} |_{x+\Delta x}$
 Gravity acting on the fluid = $(L W \Delta x) \rho g \cos \beta$.

Now as earlier we have seen we have done the shell momentum balance for doing such kind of momentum analysis and here also we will do the shell momentum balance and in that we can say the governing equation is rate of momentum in minus rate of momentum out plus sum of the forces acting on the volume element this is equals to rate of momentum accumulation, right?

So this general governing equation is applicable for momentum balance applications, right? So in that case we can say that rate of z momentum in by convection is equals to w times delta x times v_z into rho v_z at z is equals to 0 rate of z momentum in by convection is equals to w times delta x times v_z into rho v_z at z is equals to L, right? This is out not in in was there this is momentum out and rate of momentum in by molecular transport this is equals to L into w into tau xz at the phase x and rate of momentum out by molecular transport that is equals to L w tau xz at the phase x plus delta x, right?

And some more gravity acting on the fluid is equals to L w delta x times rho g cos beta, right? L w delta x that is the volume element into rho whose volume is g cos beta, right? Is the gravity acting on this, right?

(Refer Slide Time: 29:27)

Now if this is understood I hope with this beginning we will move for what to the next but before that let us also have a look so that in the next time we do not have to so this is the actual which we have taken the volume element like this, thickness we have taken Δx z direction is this perpendicular to this direction is y which we have taken as w, right?

So our volume element has become w into L into Δx , right? So this our volume element has become and and we are doing shell momentum balance across this volume element, right? So we stop it today here, next class we will do the but keep in mind that this thing we are not going to do again, right? So next time we will do the subsequent we have already done what is momentum out molecular momentum and convective momentum in and out and the gravitational force acting on it that we have shown, right? And we have also assumed it to be a steady flow steady state so that part we will keep in mind, thank you.
