Searle system      Couette system

Visual encyclopedia

IIT KHARAGPUR      NPTEL ONLINE CERTIFICATION COURSES      Jayeeta Mitra

So, rotational viscometer this is very important measurement method of viscosity, because it can handle very well the Newtonian as well as the non-Newtonian fluids. The specialty is that the measurement method is like that in these rotational viscometers, the fluid is generally getting shared between 2 component of the measuring system. And they if the agitation is being done in the rotational system so, the shear rate will be actually depend or will be proportional to the rotational speed of the system ok. So, using this we can measure the shear stress for different changing shear rates and also what we can do is we can apply the shear rate for varying length of time.

So, the effect of time will also be observed on the fluid; that is why we can handle the different kind of non-Newtonian fluid which can behave differently over a range of shear rate or maybe constant shear rate for the prolong time. So, that is why this is very useful;

and this kind of system the rotational viscometers are of different kind of geometries, but the two most common that we will discuss. So, one is the kind of rotational system where two concentric cylinders are there, the inner cylinder is rotated is generally rotated and the outer is fixed.

So, this is called Searle type systems and the other where the inner cylinder is fixed and the outer is being rotated that is called the Couette type system ok. So, now, we will see that any of this kind of rotational system we used for measurement. The basic principle will remain same. That is the torque required to move the inner cylinder at a constant speed and the shear stress that the fluid will exert on the rotating element will be balanced and that will be similar for both kind of system. So, we will see that how we can measure those thing.

(Refer Slide Time: 04:12)

**Rotational Viscometers**

**Concentric Cylinder Viscometers:**

- ✓ assumptions for mathematical model development
- 1. Flow is laminar and steady.
- 2. Radial and axial velocity components are zero.
- 3. The test fluid is incompressible.
- 4. The temperature is constant.
- 5. End effects are negligible.
- 6. There is no slip at the wall of the instrument.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Jayeeta Mitra | Department

So, rotational viscometer or the cylindrical concentric cylinder viscometer; again based on certain assumptions which are more or less we have discussed in the previous measurement methods. So, flow will be laminar and steady so that we can get the constant velocity and in the laminar flow. There will be no radial and axial velocity components here only the rotational viscosity will be considered. The test fluid should be incompressible so, that we can take the density row is constant.

Finally, the temperature is also constant here because the temperature fluctuation can cause viscosity fluctuation as well and end effects are negligible. There is no slip at the wall of the instrument is being considered.

(Refer Slide Time: 05:29)

**Rotational Viscometers**

✓ Principle:

$$M = 2\pi r h \tau r$$

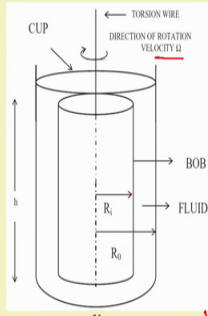

$$\tau = \frac{M}{2\pi r^2 h}$$

$$\tau_i = \frac{M}{2\pi R_i^2 h}$$

$$\dot{\gamma} = -\frac{dw}{dr} = -r \frac{d\omega}{dr} = f(\tau)$$

or  $d\omega = -\frac{dr}{r} f(\tau)$

$$-\frac{d\tau}{\tau} f(\tau) = \frac{1}{2} \left(\frac{M}{2\pi h}\right)^{1/2} r^{-3/2} dr = -\frac{1}{2} \left(\frac{M}{2\pi h}\right)^{1/2} \tau^{-1/2} d\tau$$

$$\left(\frac{M}{2\pi h}\right)^{1/2} = \frac{1}{2} f(\tau) \frac{d\tau}{\tau}$$

Jayeeta Mitra  
ACEE Dept

So, the principle we will see this is a cup which is steel here that is being fixed with the with some arrangements, but the inner cylinder or the bob, that is rotating with the constant angular velocity and inner radius of bob is  $R_i$  outer radius of the outside cup is the inner radius of the outside cup that is  $R_o$ . That means, fluid will be in between this  $R_i$  to  $R_o$  the fluid which will be getting sheared that will be in between these 2 concentric cylinder; so therefore, as the bob will rotate.

So, continuous shearing or the change of the shear rate can be provided on the fluid kept in between and also for different time it can be applied. Now we will see the torque required to rotate this inner cylinder at a constant angular velocity will be  $M$  let us say this torque is capital  $M$  and the force that will be opposed that torque will be the shear force, which is the liquid held here will provide. So, let us first see that if you want to make a force balance we can write that this torque  $M$  will be equivalent to  $2\pi r h$ . This is the area where the shear stress  $\tau$  is being applied and it is acting let us say at a distance  $r$  from the centre. So, this will be the torque.

So, we can write that torque will be equal to  $M$  by  $2\pi r^2 h$ . Now since the inner cylinder is inner cylinder is rotating and the outer is fixed, just if we go back to if we go

back to the previous diagram, here we can see that the shear stress or the shear rate we not be similar in all the annular spaces. So, it will be higher at the inner radius because that is the inner cylinder is rotating with a constant angular speed; however, the stress at the outer wall will be or the outside of that liquid level, which is which is in contact with the sixth fix cylinder that will be less. So, here if you want to measure the stress that is coming on the inner cylinder; so we can write this as  $\tau_i$  this is equal to  $M$  by  $2\pi R_i^2$  into  $h$ , where  $h$  is the height of the liquid film ok.

Now with that we also try to get the expression of shear rate, because to have the viscosity, we want to get the relation between the shear stress and shear rate. So, the expression of shear rate  $\dot{\gamma}$  it is this one  $\frac{dv}{dr}$ , because as we move on to radial direction the velocity will be decreasing, because the outer cylinder is still and the inner is rotating that is why  $\dot{\gamma}$  will be like this.

Now we can replace this velocity  $v$  to tangential velocity with the angular speed. So, we can write this equal to  $\omega r$  into  $r$  ok. Now we also know that  $\dot{\gamma}$  will be a function of  $\tau$  that is shear stress. So, we can write the differential angular speed  $\frac{d\omega}{d\tau}$  that is equal to  $\frac{dr}{r}$  into  $f$  of  $\tau$  right; now what we do is, we need to find the expression of  $dr$  from this relation. So, what we can do is, since  $r^2$  this is equal to  $M$  by  $2\pi h$  into  $\tau$ .

So,  $r$  will be equal to  $M$  by  $2\pi h$  into  $\tau$  to the power half. So,  $dr$  we can take this as a constant, and then can take  $\tau$  to the power minus half and differentiate this with respect to  $d\tau$ . So, the expression we will get that get is some constant  $M$  by  $2\pi h$  to the power half into  $\tau$  to the power minus  $\frac{3}{2}$  and then we put that expression here. So, this will be ok. So,  $\frac{dr}{r}$  into  $f$  of  $\tau$  minus that will half of  $M$  by. So, this will be  $M$  by  $2\pi h$  to the power half  $\tau$  to the power minus  $\frac{3}{2}$  into  $d\tau$  and  $r$  we can get from this expression. So,  $1$  by this will be  $M$  by  $2\pi h$  to the power half and this  $\tau$  we can take it here. So, this will be  $\tau$  to the power half.

So, finally, this will be getting cancelled and we can get and here also was  $f$  of  $\tau$ . So, we are getting finally, one half of  $f$  of  $\tau$  into  $d\tau$  by  $\tau$  ok. So, this expression finally, we got.

(Refer Slide Time: 16:47)

### Rotational Viscometers

✓ Principle:

$$d\omega = \frac{1}{2} \frac{f(\tau) d\tau}{r}$$

$$\int_{\omega_1}^{\omega_2} d\omega = \frac{1}{2} \int_{\tau_1}^{\tau_2} \frac{f(\tau) d\tau}{r}$$

Jayeeta Mitra  
ACEE Dept

So, let us now write it clearly that  $D \omega$  this is equal to one half of  $f \tau d \tau$  by  $r$  that.

We are getting now since  $\omega$  which is angular velocity of the inner cylinder, that is that may vary from  $\omega$  that constant at  $R_i$  to  $\omega$  at the  $R_o$ . So, similar things will happen with the stress as well. So, stress will be max at  $R_i$  and it will be minimum at  $R_o$ . So, we can integrate this as. So, half of  $\tau_i$  to  $\tau_o$ , then  $f$  of  $\tau$  by  $\tau$  into  $d \tau$  ok. Now solution of this kind of a problem will depend on function of  $\tau$  function of  $\tau$  now function of  $\tau$  will again vary with different kind of solution. This if it is Newtonian then there will be shear rate will be shear stress by dynamic viscosity; if it is power law fluid then the relation will be different from shear stress divided by  $k$  to the power  $1/n$  like that. So, as  $f \tau$  will vary for different kind of a solution different kind of fluid food sample, then solve of this equation the final result of this equation will be varying.

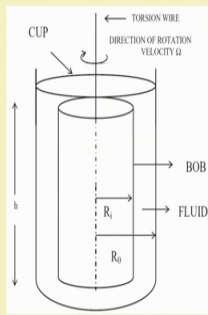

(Refer Slide Time: 19:01)

### Rotational Viscometers

✓ **Principle:**

- ❑ The inner cylinder rotates at a constant angular velocity ( $\Omega$ ) and the outer cylinder is stationary,
- ❑ the instrument measures the torque ( $M$ ) required to maintain this constant angular velocity of the inner cylinder.
- ❑ The opposing torque comes from the shear stress exerted on the inner cylinder by the fluid.

✓ **Force Balance:**

Concentric cylinder viscometer  
(source: Sahin and Gulum Sumnu 2006)

IIT KHARAGPUR

NPTEL ONLINE  
CERTIFICATION COURSES

Jayeeta Mitra  
ACEE Dept.

So, now, we will see the cases ok. So, this we have we have already solved this doing the force balance so we have come to this stage now.

(Refer Slide Time: 19:08)

### Rotational Viscometers

✓ **Force Balance:**

❑ General expression for the angular velocity of the inner cylinder as a function of the shear stress in the gap

❑ Solution of the above Eq. depends on  $f(\tau)$ , which depends on the behaviour of the fluid. Newtonian—

❑ For a power law fluid--

$$M = 2\pi r h r \tau = 2\pi h r^2 \tau$$

$$\tau = \frac{M}{2\pi r^2 h}$$

$$f(\tau) = \dot{\gamma} = \frac{\tau}{\mu}$$

$$\Omega = -\frac{1}{2\mu} (\tau_o - \tau_i)$$

$$= +\frac{1}{2\mu} \frac{M}{2\pi h} \left( \frac{1}{R_o^2} - \frac{1}{R_i^2} \right)$$

$$= \frac{M}{4\mu\pi h} \left( \frac{1}{R_o^2} - \frac{1}{R_i^2} \right)$$

$$f(\tau) = \dot{\gamma} = \left( \frac{\tau}{\mu} \right)^{1/n}$$

$$\int_{\Omega}^0 d\omega = \frac{1}{2} \int_{\tau_i}^{\tau_o} f(\tau) \frac{d\tau}{\tau}$$

$$\Omega = \frac{M}{4\pi\mu h} \left( \frac{1}{R_o^2} - \frac{1}{R_i^2} \right)$$

$$\Omega = \frac{n}{2k^{1/n}} \left( \frac{M}{2\pi h R_i^2} \right)^{1/n} \left[ 1 - \left( \frac{R_i}{R_o} \right)^{2/n} \right]$$

IIT KHARAGPUR

NPTEL ONLINE  
CERTIFICATION COURSES

Jayeeta Mitra  
ACEE Dept.

And if it is Newtonian, then what we can do is we know that for Newtonian fluid the function of tau. So, that is such that gamma dot will be tau by mu. So, will put it here integrate this over ohm to 0 from for tau i at R i and tau o at Ro. So, here it will be minus 1 by 2 mu into tau 0 minus tau i. Again this tau is related with the torque. So, the expression was tau will be equal to M by 2 pi r square h. So, we can write it like this 1 by

$2\mu$  into  $M$  by  $2\pi h$  by  $r_i^2$  minus  $R_o^2$  if we take this as plus right. So, finally, we are getting this equation that angular speed that is equal to  $1$  by  $4\mu\pi h$  into  $1$  by  $R_i^2$  minus  $1$  by  $R_o^2$  ok. So, from this we can get the idea of the dynamic viscosity  $\mu$  and next we can see the case.

So, here was  $M$  finally, we are getting this equation ohm equal to  $M$  by  $4\pi\mu h$  by  $R_i^2$  minus  $1$  by  $R_o^2$ . Now let us see if it is Newtonian if it is non-Newtonian then considering power law fluid, we will get this kind of expression. So, for this what we need to do is, we will take this  $f$  tau the function that is  $\dot{\gamma}$  ok. So, this is actually shear rate so, that that we can take in this way tau by constant  $k$  to the power  $1$  by  $n$ . So, then putting this into this equation function  $f$  and in a similar way integrating putting the values from this equation tau, and the torque required we are getting this equation that is ohm equal to  $n$  which is the flow behavior index of the power law by  $2k$  to the power  $1$  by  $n$  the consistency index. Then  $M$  divided by  $2\pi h r_i^2$  to the power  $1$  by  $n$  into  $1$  minus  $r_i$  by  $r_o$  to the power  $2$  by  $n$ .

So, in this way we can we can now plot the shear stress and shear rate and we can we can find that what will be the relation between them and then calculate the dynamic viscosity.

(Refer Slide Time: 24:11)

**Rotational Viscometers**

✓ **Simple Shear Approximation:**

- small gap between the cylinders compared to the radius
- shear stress can be taken as constant

$$\dot{\gamma}_i = \frac{\Omega R_i}{R_o - R_i} = \frac{\Omega}{\alpha - 1} \quad \alpha = R_o / R_i$$

$$\tau_{ave} = \frac{1}{2} (\tau_i + \tau_o) = \frac{M(1 + \alpha^2)}{4\pi h R_o^2}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Jayeeta Mitra | ACE Dept.

So, if we look into the simple shear approximation cases. So, the small gap between the 2 concentric cylinder is taken very small compared to the radius and then what we do is, we take the shear stress as constant and we can measure the shear rate  $\dot{\gamma}$  as

equal to  $\omega R_i$  that is if we are measuring at a distance  $R_i$  and the angular speed is constant that is  $\omega$ .

So, the distance it can move is  $\omega R_i$  divided by  $R_o - R_i$  that is the radial distance where the liquid is. So, that is equal to  $\omega$  by  $\alpha - 1$ , where this  $\alpha$  is equal to  $R_o / R_i$ . And here we can take the shear stress as average that is half of  $\tau_i$  which is at the inner cylinder plus  $\tau_o$  which is at the outer cylinder, and that will be equal to  $M$  into one plus  $\alpha$  square by  $4\pi h$  into  $R_o$  square. So,  $\tau_i$  and  $\tau_o$  we have taken from that relation where we are relating torque with the shear stress.

(Refer Slide Time: 26:04)

**Rotational Viscometers**

- ✓ **Newtonian Approximation:**  $\tau_i = \frac{M}{2\pi h R_i^2}$       $M = 2\pi r h r \tau = 2\pi h r^2 \tau$
- ✓ Shear stress at the inner cylinder
- ✓ rearrangement gives Margules equation:  $\Omega = \frac{M}{4\pi \mu h} \left( \frac{1}{R_i^2} - \frac{1}{R_o^2} \right)$
- ✓ **Power Law Approximation:**
- ✓ Shear stress at the inner cylinder
- ✓ rearrangement gives Margules equation:  $\dot{\gamma}_i = 2\Omega \left( \frac{\alpha^2}{\alpha^2 - 1} \right)$
- ✓  $\dot{\gamma}_i = \left( \frac{2\Omega}{n} \right) \left( \frac{\alpha^{2/n}}{\alpha^{2/n} - 1} \right)$

IIT KHARAGPUR     NPTEL ONLINE CERTIFICATION COURSES     Jayeeta Mitra     ACE Dept.

And if for the Newtonian approximation we can take  $\tau_i$  as  $M$  by  $2\pi h R_i$  square by that relation ok. So, shear stress at the inner cylinder will be governed by this law  $M$  by  $4\pi \mu h$   $(1/R_i^2 - 1/R_o^2)$ . And rearranging this we can get the expression of  $\dot{\gamma}_i$  that is called the Margules equation  $\dot{\gamma}_i$  that is equal to  $2\omega$  into  $\alpha^2$  by  $\alpha^2 - 1$  and if we take the power law approximation. So, shear stress at the inner cylinder will be  $\dot{\gamma}_i = (2\omega/n) (\alpha^{2/n} / (\alpha^{2/n} - 1))$  and again ok.

(Refer Slide Time: 27:24)

### Measurement of rheological properties

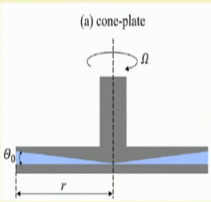

✓ **Cone and Plate Viscometers:**

- angular velocity of cone- $\Omega$ .
- annular fluid transmits torque to the plate.
- angle  $\theta$  is small ( $<5^\circ$ ), shear stress and shear rate are uniform over the fluid (Steffe, 1996).
- shear thinning fluids and plastic fluids.

✓ at higher shear rates, low-viscosity fluids may be thrown out of the gap.

✓ Constant temperature maintenance is more difficult for cone and plate geometries than for concentric cylinders.

✓ Materials containing large particles cannot be studied because of the small gap between the cone and the plate.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Jayeeta Mitra | AGEE Dept.

So, like this way we can get the shear rate versus shear stress data in case of the rotational viscometer and can measure the viscosity, we will solve a problem at the end of the class and next will move on to another measurement method, that is cone and plate viscometer.

So, from the diagram we can see that it is another kind of rotational viscometer. So here, it is another kind of rotational viscometer and here a cone is there on a circular flat plate; in a way that axis will be perpendicular on the plate, and the apex is on the surface of the plate. This cone is moving with the angular velocity and the gap between the cone and plate will be filled by the liquid.

So, this kind of arrangement is very much suitable for the shear thinning behavior and the plastic fluid behavior. The gap is usually very less the angle which it makes the cone make the angle with the parallel plate and that angle is generally very small  $\theta$  generally kept lower than 5 degree ok. So, if it lower than 5 degree then it is considered that the shear stress and shear rate in the in the gap or the angular space or the space for the fluid is, that will be exposed to the constant shear rate and constant shear stress.

So, we can handle the shear thinning fluid and plastic fluid here, but then also carefully we have to do this because there is a chance that the shear thinning fluid will come out when we operate at a higher shear stress or shear rate. So, constant temperature maintenance here is another problem, because of the plate geometry and material

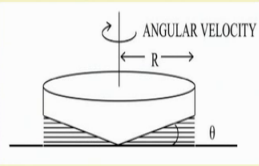

containing the large particle cannot be used here, because the place available to put the liquid is very small.

(Refer Slide Time: 30:21)

**Cone and Plate Viscometers**

✓ Principle:  $\dot{\gamma} = \frac{r\Omega}{r \tan\theta} = \frac{\Omega}{\tan\theta}$

$$\int_0^M dM = \int_0^R (2\pi r dr) \tau r$$

$$\tau = \frac{3M}{2\pi R^3}$$

(source: Sahin and Gulum Sumnu 2006)

Then rheological properties can be determined after selection of a specific model:

For a Newtonian fluid:  $\frac{3M}{2\pi R^3} = \mu \frac{\Omega}{\theta}$

For a power law fluid:  $\frac{3M}{2\pi R^3} = \mu \left(\frac{\Omega}{\theta}\right)^n$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Jayeeta Mitra | AGEE Dept.

So here also we will see that; what is the principle of determining the viscosity here. So, here the cone is rotating with the angular velocity constant angular velocity and we measure the shear rate  $\dot{\gamma}$  by the amount it moves in the angular direction that is if we measure at a distance at a radial distance  $r$ . So,  $r$  into  $\dot{\theta}$  divided by  $r$  into  $\tan \theta$  that the  $\tan \theta$  where  $\theta$  is the angle between the cone and the plate and if the  $\theta$  is very small instead of  $\tan \theta$ , we can take only  $\theta$  here ok. So, we are getting  $\dot{\gamma}$  by  $\tan \theta$  as the shear rate here. So since, here also the torque will not be same in all the places, it will vary from centre where  $R$  equal to 0 to the  $R$  equal to  $R$  where the outside radius or the whole radius of the cone; so 0 to  $M$   $dm$  if we indicate the torque.

So, here it will be 0 to  $R$  again  $2\pi r dr$ . So,  $dr$  a small fluid element here we are considering and the  $\tau$  which is the shear stress that is being applied by the fluid to oppose the rotational movement, and it is acting at a distance  $r$ . So, this will be there. So, then from here we can find this expression  $\tau$  will be equal to  $3M$  by  $2\pi r^3$ . Here we can get  $\pi r^2 dr$ . So, it will be  $r^3$  by 3 that 3 will come here. So, we are getting  $3M$  by  $2\pi r^3$ . So, this will be the stress ok. So, then the rheological properties can be determined after selection of the specific model. So, from the specific

model, if we plot the shear stress versus shear rate  $\dot{\gamma}$  we can get a curve from which the viscosity can be calculated. So, for the Newtonian fluid for the Newtonian fluid we can get the relation  $M = 2\pi r^3$  that is equal to.

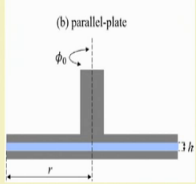

This is shear stress that is equal to  $\mu \dot{\gamma}$  which is the viscosity into ohm by theta, here we can we have put directly the shear rate  $\dot{\gamma}$ ,  $\tan \theta$  has been reduced to  $\theta$  as the angle is very small and if it is for the for the non Newtonian fluid that is a power law fluid. So, we will take shear stress  $M = 2\pi R^3$  that is equals to  $\mu \dot{\gamma}$  into ohm by theta to the power n.

(Refer Slide Time: 34:46)

**Measurement of rheological properties**

✓ **Parallel Plate Viscometers :**

- angular velocity of the upper plate= $\Omega$ , bottom plate is stationary.
- shear rate is not constant in the fluid during deformation but changes as a function of distance from the center  $r$

(b) parallel-plate

$$\dot{\gamma} = \Omega \frac{r}{h}$$

$$\int_0^M dM = \int_0^R (2\pi r dr) \tau r$$

$$\tau_R = \frac{M}{2\pi R^3} \left[ 3 + \frac{d \ln M}{d \dot{\gamma}_R} \right] \approx \text{Rabinowitsh-Mooney equation}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Jayeeta Mitra | ACE Dept. | 10

So, another similar kind of measurement method is the parallel plate viscometer, here the 2 parallel plates are there; one is a rotating plate which is having a constant rotational movement and the lower plate which is fixed, in between there is liquid of height  $h$  is kept and the radius is  $r$ . So, as the upper plate is circular plate that is rotating, the stress is offered by the liquid which is kept in between. So, here the shear rate is not constant in the fluid during the deformation, but changes as a function of distance from the centre. So, again  $\dot{\gamma}$  will be  $r$  divided by  $h$ .

So, again we will integrate in a similar fashion as we did for the cone and plate viscometer, and here we can get the expression of this kind where  $\tau_R$  that is the shear stress that is equal to  $M$  by  $2\pi r^3$  into  $3 + \frac{d \ln M}{d \dot{\gamma}_R}$ . So,  $\tau_R$  that is the shear stress at the extreme outer radius and this  $\dot{\gamma}_R$  is the shear

rate there.  $M$  is the torque that is equal to move the upper circular plate at to rotate it at a constant angular speed  $\omega$ .

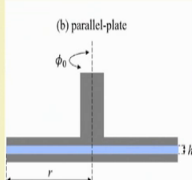

(Refer Slide Time: 36:59)

### Parallel Plate Viscometers

✓ For a Newtonian fluid :  $\tau = \mu \dot{\gamma} = \mu \frac{\Omega r}{h}$

$$\frac{2M}{\pi R^3} = \mu \frac{\Omega r}{h}$$

✓ For a Non-Newtonian fluid :  $\frac{M(3+n)}{2\pi R^3} = k \left( \frac{\Omega r}{h} \right)^n$

$$\tau_R = \frac{M(3+n)}{2\pi R^3}$$

(b) parallel-plate

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Jayeeta Mitra | ACEF Dept.

So, this is called the Rabinowitsh Mooney equation and for a Newtonian fluid we will just apply the linear relation between shear stress and shear rate put it in that equation. So, we are getting this expression finally. And if we are dealing with a non Newtonian field, we are getting this kind of expression where we take consistency index into account into  $r$  by  $h$  to the power  $n$ . So,  $\tau_R$  we getting as  $M$  into  $3 + n$  by  $2 \pi R^3$ .

(Refer Slide Time: 37:45)

### Measurement of rheological properties

✓ **Single-Spindle Viscometers (Brookfield Viscometer):**

- Variable -> spindle sizes and speed
- spindle selection-> trial and error.
- viscosity of Newtonian fluids (calibrated with Newtonian oils).
- The steady-state deflection is noted and a conversion chart is provided to estimate the apparent viscosity under the test conditions. determine apparent viscosity at different speeds (shear rates), but shear stress–shear rate data cannot be presented.
- The results are normally presented in the form of apparent viscosity against rotational speed.
- time dependency can be checked.

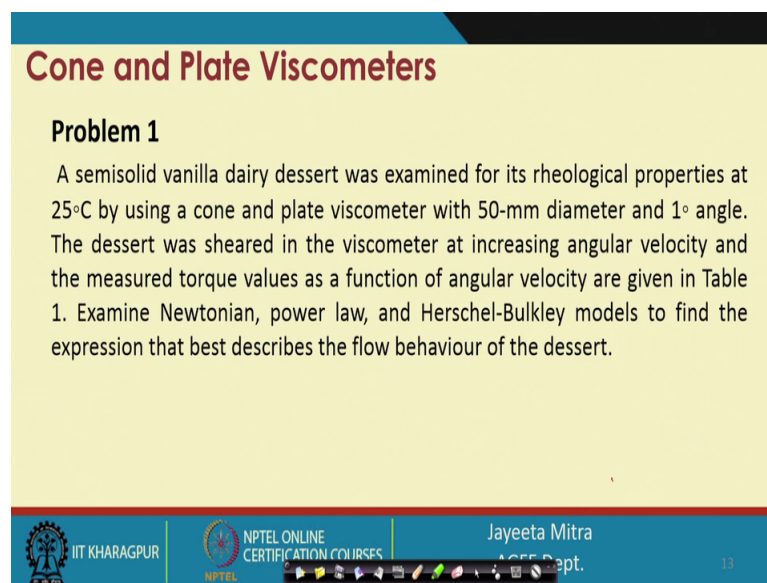

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Jayeeta Mitra | ACEF Dept.

So, there are other methods like Single Spindle Viscometres which is also called the Brookfield viscometer this is the pictorial view of that.

This spindle is rotating continuously in the in the liquid; spindle size and the speed can be varied here to measure its affect and the spindle selection is done by trail and error by doing some initial measurement. And viscosity of the Newtonian fluids is used to calibrate this generally the Newtonian oil is used, and the viscosity of Newtonian fluid can be measured very well by this Brookfield viscometer. The steady state deflection is noted and a conversion chart is provided to estimate the apparent viscosity under the test condition. So, the determination of the apparent viscosity at different speed that is different shear rate can be done, but the shear stress shear rate data cannot be presented; so only apparent viscosity that can be calculated.

(Refer Slide Time: 39:29)

**Cone and Plate Viscometers**

**Problem 1**

A semisolid vanilla dairy dessert was examined for its rheological properties at 25°C by using a cone and plate viscometer with 50-mm diameter and 1° angle. The dessert was sheared in the viscometer at increasing angular velocity and the measured torque values as a function of angular velocity are given in Table 1. Examine Newtonian, power law, and Herschel-Bulkley models to find the expression that best describes the flow behaviour of the dessert.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Jayeeta Mitra | AGEE Dept. | 13

So, now we will do one problem quickly on that. Let us take a semisolid vanilla dairy dessert. This was examined for the rheological. Shall I stop here?

Ok.

In next lecture (Refer Time: 40:12).

Ok.

Alright (Refer Time: 40:15).

So, we will stop here. And, in the next class we will do some problem solving on measuring the rheological parameter of the fluid food.

Thank you.
