Lecture – 35
Structural Design of Drop Spillways – 2

So, welcome students, so, this is our 5th class on the Design of Drop Spillway, we have already designed the drop spillway and we have in the last class we have already discussed about how to estimate the horizontal pressures.

(Refer Slide Time: 00:38)

Course Content - Week 7

- Lecture 1: HYDRAULIC DESIGN OF DROP SPILLWAY
- Lecture 2: HYDRAULIC DESIGN OF DROP SPILLWAY IN DIFFERENT FLOW CONDITIONS
- Lecture 3: HYDRAULIC DESIGN COMPONENTS
- Lecture 4: STRUCTURAL DESIGN OF DROP SPILLWAY-1
- Lecture 5: STRUCTURAL DESIGN OF DROP SPILLWAY-2**

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

Here we will be discussing the structural design of drop spillway part - 2.

(Refer Slide Time: 00:46)

STRUCTURAL DESIGN OF DROP SPILLWAY

Purpose:

To evaluate the strength & stability of different parts of the drop spillway against:

1. Uplift pressure
2. Contact pressure
3. Piping failure
4. Overturning

The diagram illustrates the structural design of a drop spillway. It shows a cross-section of the spillway structure, including the backfill, the spillway face, and the saturated foundation material. Key features labeled include the Saturation Line, Tailwater Elev., Vertical contact pressure (V), Hydrostatic Uplift pressure, and Piping. The diagram shows water flowing over the spillway face and the resulting pressures and potential failure modes at the base of the structure.

Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

This lecture highlights the evolution of strength and stability of different parts of drop spillway against uplift pressure, contact pressure, piping failure, and overturning.

What is the uplift pressure? The uplift pressure happens because if the foundation metal gets saturated. So, pore water pressure develops and this hydrostatic pressure acts upward. So, if this hydrostatic pressure acts upward then it creates one negative pressure in the stability.

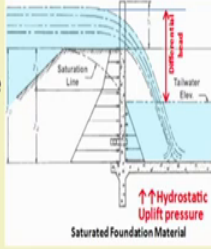

Second is contact pressure, the contact pressure is nothing, but it is the vertical pressure which is acting at the contact surface between the structure as well as the saturated foundation. So, you can see the contact pressure is given by the notation V , which is acting at the base of this foundation and depending on the location of this V that is vertical contact pressure the overturning of the structure will happen. If it acts at exactly or the centroid of this base section then there is more stability otherwise there will be overturning

Then the piping failure mostly occurs at the base of the foundation which is contacting between the structure and the saturated foundation material, you can see here the piping failure takes place along the contact surface between the structure and the saturated foundation material. So, all the details we will be discussing in this class.

(Refer Slide Time: 03:04)

1. UPLIFT PRESSURE ON DROP SPLYWAY

- Upward hydrostatic pressures on the base is due to:
 - ✓ The pressure transmitted through the seeping water in the saturated foundation material that reduces the self-weight of the structure
 - ✓ Differential head between the elevations of water surfaces above & below the spillway (see Figure)
- For earth foundations: Uplift pressures are assumed to exist over the entire base area of the spillway
- Uplift pressure can be roughly estimated by using the “Line of Creep theory”
- For stability, the sum of the weight of the structure & all the vertically downward forces acting on it, must be greater than the uplift force

The diagram illustrates a cross-section of a drop spillway. On the left, water flows over the spillway crest. On the right, the water level drops to a lower elevation, labeled as the 'Tailwater level'. A dashed line represents the 'Saturation Line' within the foundation material. A red arrow points upwards from the base of the spillway, labeled 'Hydrostatic Uplift pressure'. The foundation material is labeled 'Saturated Foundation Material'.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. B. Sahoo, School of Water Resources, IIT KHARAGPUR

The upward hydrostatic pressure on the base is due to the pressure transmitted through the seeping water in the saturated foundation material that reduces the self weight of the structure. And this is mostly caused because of the differential head you can see this figure at the option site there is depth of water and at the downstream side rates tail water and the difference between these two water surface elevations is the differential head. And this differential head gives additional energy head and that is exerted on the saturated foundation material. So, because of that the pore water pressure the soil pore water pressure develops.

For earth foundations this uplift pressures are assumed to be existing over the entire base area of the spillway. Uplift pressure can be roughly estimated by using the line of Creep theory. The line of Creep theory talks about how the water moves are the contact surface between the structure and the foundation metal, you can see the line of creep goes like this as I am marking here on this figure.

So, along this line generally the water seeps and the piping phylogeny occurs. So, by using this line of Creep theory along this contact surface we estimate the uplift pressure. These uplift pressures are generally computed based on what are the water surface elevations at different contact surfaces along this line the creep line.

But stability the sum of the weight of the structure and all the vertically downward forces acting on it must be greater than the uplift pressure. If the uplift pressure is more

naturally the structure will float. So, generally the uplift pressure is a negative pressure, which has to be deducted from the vertical pressure during all these force calculations.

(Refer Slide Time: 05:35)

2. CONTACT PRESSURE

- ❑ Contact pressure occurs due to the vertical & horizontal loadings at the contact surface of the structure & foundation material.
- ❑ Should be computed for three loading conditions:
 - ✓ Before any backfill has been placed around the spillway
 - ✓ After all the backfill has been placed with no flow over spillway
 - ✓ The spillway operating at design discharge capacity

Now, coming to contact pressure, the contact pressure occurs due to the vertical and horizontal loadings or the contact surface of the structure and foundation material. You can see this figure; this is a very important figure to understand this figure shows the plan of base area. You can see this figure, this is the head wall and this is my upon section and the whole figure on the top shows the plan of the base area. And here I am choosing the axis the o axis just at the bottom corner of this upstream part of this.

So, this is my upstream edge and my axis is o o you can it is assumed that the whole structure is almost rectangular it has a width of d and length of b so; the centroid passes through d by 2 and b by 2 . So, this is my centroid which is just exactly at the center of this rectangle and my vertical forces are acting at this location which is at a distance e from the centroid. So, this is my e distance and z is the distance between this upstream edge and the point of the line parallel line joining the point where V is acting.

So, at this section V is acting that is the contact force that the summation of all these vertical forces minus the uplift pressure force. So, is called as eccentricity here, if these are acting exactly at the centroid of this base they naturally the structurally more stable , but it is acting at a distance of e from the centroid which is called eccentricity naturally there will be momentum will be occurring. So, that it call as like your bending moment

you have study might are studied so, that is lust like a bending moments and generally that will cause overturning of the structure. So, this e can be either this positive side to the centroid axis or it will be towards negative side that we in this side of this centroid.

So, before going to calculate the contact pressures you have to understand this figure and these contact pressures should be computed for 3 loading conditions. Before any backfill has been around the spillway, after all the backfill has been placed with no flow over spillway and the spillway operating at design discharge capacity. So, these are the 3 engineering condition generally we consider for calculating the contact phases.

(Refer Slide Time: 09:04)

QUANIFICATION OF CONTACT PRESSURE

□ Contact pressure for a rectangular base can be computed as (see Figure)

$$P_1 = \frac{V}{A} \left(1 \pm \frac{6e}{d} \right)$$

where,

- P_1 = Contact pressure at upstream or downstream edge of base (Pa)
- V = Sum of the vertical loads acting on the structure (N)
- b = Base width (m)
- d = Base length (m)
- $A = b \times d$ = Base area (m²)
- $e = d/2 - z$ = Eccentricity (m)

$V =$ Weights of all the concrete ↓
 + earth above footings ↓
 + water above any part of the structure ↓ + uplift ↑.

The diagram illustrates the quantification of contact pressure on a rectangular base. It shows a 'Top View' of a rectangle with width 'b' and length 'd'. The centroid is at the center, and the resultant vertical load 'V' acts at a distance 'e' from the centroid. The distance from the centroid to the upstream edge is 'z'. The 'Side View' shows the structure with an apron, and the 'Plan of base area' shows the O-axis and the location of the resultant load 'V' relative to the O-axis.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. B. Sahoo, School of Water Resources, IIT KHARAGPUR

For calculating the contact pressure for a rectangular base we can use the equation P_1 equal to V by A into 1 plus minus $6e$ divided by d . Here e is the eccentricity, d is the width of this base and V is the sum of all the vertical loads acting on the structure, which are equal to weights of all the concretes, earth above footings, water above any part of the structure and these are acting downward minus the uplift pressure.

So, here the uplift pressure is working acting upward so, it will be minus. Then you can calculate what is the resultant vertical load on this? And if it is acting at this central location then it be more stable if it is acting at a distance e from the centroid that is eccentricity naturally there will be turning our momentum will be there. Here A is equal to the base area that equal to computed as b into d , if e is equal to 0 in this equation

naturally P_1 it will be equal to V by A that equal to force data area that is equal to your pressure.

(Refer Slide Time: 10:46)

Moment of Vertical Loads, M_v

- Select the **0-0 axis** along the upstream edge of the base area at the elevation of the bottom of the apron.
- Let v_i = magnitude of the i th part of the vertical load or weight
- L_i = perpendicular distance between the line of action of the load v_i and the **0-0 axis** (see Figure).
- Then the moment, M_v , of all such parts of the total vertical force, about the **0-0 axis** is given by:

$$M_v = \sum v_i L_i = v_1 L_1 + v_2 L_2 + \dots + v_n L_n$$

$$V = \sum v_i = v_1 + v_2 + \dots + v_n$$

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

Now, we have to compute the moment of vertical loads M_v , for this as to select the $0-0$ axis are seen this figure, from this $0-0$ axis along the upstream edge of the base area the elevation of the bottom of the apron let this O . Let V_i be the magnitude of the i th part of the vertical load or weight, because there are different vertical loads, these vertical loads can be because of the head wall it can be because of the apron it can be because of the backfill materials. So, these are different vertical load components, so, these are called as V_i and they are acting at a location perpendicular distance between the line of action of the load V_i and the axis o that is equal to L_i .

Then the moment, M_v of all such parts of the total vertical force about the $0-0$ axis can be given by this equation you know that momentum equal to our moment equal to force into the length. So, M_v equal to $\sum V_i L_i$ that equal to $V_1 L_1$ plus $V_2 L_2$ plus $V_n L_n$, where V_i are the different part loads, different part vertical loads and total resultant vertical load would be equal to summation of all these vertical forces acting on the base of the structure.

(Refer Slide Time: 12:29)

Moment of Horizontal Loads, M_h

- Let h_i = magnitude of the i th part of the horizontal load
- y_i = vertical distance from the line of action of the load h_i through its centroid to the 0-0 axis
- Then the moment, M_h , of all such parts of the total horizontal force H about the 0-0 axis is given by:

$$M_h = \sum h_i y_i = h_1 y_1 + h_2 y_2 + \dots + h_n y_n$$

$$H = \sum h_i = h_1 + h_2 + \dots + h_n$$

d
d/2
d/2
b

Side View
Apron
e
z
O axis

Plan of base area

Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

Then there could be the horizontal loads, the horizontal loads could be because of there is static water table or the upstream side and let these vertical loads be defined as different parts. Let h_i equal to magnitude of the i th part of the horizontal load, y_i is the vertical distance from the line of action of the load h_i through its centroid to the O axis, then the moment M_h of all such parts of the total horizontal force is can be estimated similar as we have done for the vertical loads. So, your M_h will be equal to $\sum h_i y_i$ and H will be equal to summation of h_i that is the total horizontal loads.

(Refer Slide Time: 13:21)

- Then the distance ' z ' from the 0-0 axis to the point of application of the resultant vertical force V is given by:

$$z = \frac{M_v + M_h}{V} = \frac{\sum v_i L_i + \sum h_i y_i}{\sum v_i}$$

- For **stability against tension** at the base of headwall:
Eccentricity, $e = (d/2 - z) < d/6$
OR $z > d/3$ ✓
- The structure is **safe against overturning** if positive contact pressures exist over the entire base area.

z
O axis

Plan of base area

Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

Then the total moment due to vertical loads and horizontal loads can be estimated by this equation which is M_v plus M_h that equal to total moment divided by V will give you the value of z , because V is the resultant load, resultant vertical load. So, the total moment will be countered by V times z so, z is the distance from this O-O axis to the points to the line passing through this point where this V is acting.

So, you can estimate what is the distance z , by computing this z you can check for the stability again against tension. So, for stability against tension are the base of head wall we can estimate what is the eccentricity, from this figure you can see that $d/2$ equal to e plus z . So, e will be equal to $d/2$ minus z and for stability against strength so, near to design such that e should be less than $d/6$ it will solve this equation then you will get z equal to $d/3$ I will sorry z is greater than $d/3$.

So; that means, for stability against tension z should be greater than $d/3$, the structure is safe against overturning a positive contact pressure exists over the entire base area. So, depending on this position of eccentricity you can estimate whether the structure will overturn or not. So, to our the overturning you have to design such a that z is greater than $d/2$.

(Refer Slide Time: 15:25)

STABILITY AGAINST PIPING FAILURE

- ❑ Piping is defined as the **removal of material from the foundation through seepage water** as it emerges from the soil below the dam (mostly occur when water table is high).
- ❑ The velocity of seepage depends on the length of flow path.
- ❑ Failures due to piping may result from subsurface erosion or heave.
- ❑ Seepage could occur through earth foundations as:
 - Flow through the foundation material itself
 - Along the **line of least resistance**, which is the line of contact between the spillway & foundation

The diagram shows a dam cross-section with water on the upstream side and a spillway on the downstream side. A flow path is shown from the upstream water table, through the foundation, and out at the downstream toe. Labels include 'Upstream', 'Downstream', 'Pervious foundations', and 'Erosion through piping'. A small inset shows a close-up of the flow path through the foundation.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, next is stability against the piping failure, you can see from this figure that piping defined as the removal of material from the foundation through seepage water as it

emerges from the soil below the dam, on this mostly occur when the water table is high, if the upstream water table is high it creates additional water facer.

And because of this generally the what we as foundation is gets saturated and when it gets saturated the upstream pressure the water pressure which is causing the flow of our which is causing generally the saturation of this foundation. So, it will create additional pressure so, that this water will move along with the soil particles and it will make a pipe like structure and if the there is more loss of the soil materials along this pipe line then the structure will fail.

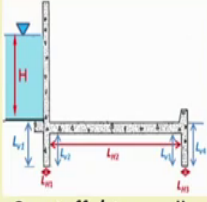

The velocity of seepage depends on the length of flow path; failures due to piping may result from subsurface erosion or heave. So, because of these the subsurface erosion causes; that means, the soil particles along this line they emerges out at the downstream section and sometimes this creates quicksand condition you might have studied already that what is quicksand condition.

The seepage could have occur through earth foundation such as flow through the foundation material itself, it can directly flow through these foundation material as shown in this figure or along the line of least resistance which is the line of contact between the spill and foundation. That means, these seepage may occur also along this contact surface as I am showing in this diagram; that means, it will pass through this line and this is called as the line of creep as we have studied in the previous slides.

(Refer Slide Time: 17:43)

STABILITY AGAINST PIPING FAILURE

- ❑ The design against piping failure is based on the **'Line of Creep Theory'**
(Postulated by: **W.G. Bligh** & further revised by **E. W. Lane**)
- ❑ **'Line of creep'** is the line of contact between the dam & cutoff / toe walls with the foundation, that produces less resistance to percolation than any other path through the foundation material.
- ❑ Majority of failure due to piping occurred along the line of creep.
- ❑ **Weighted creep length:** It is the **sum of all the steep contacts** and **one-third of all the contacts flatter than 45°** between the headwater and tail-water along the contact surface of the drop spillway & foundation.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

Now, for the stability against piping failure the design against piping failure is based on the line of Creep theory and it is postulated by W G Bligh and further revised by E W Lane so, less theory is the most advanced one so, that is why we will use the lens theory for all our designs.

The line of Creep is the line of contact between the dam and cut off or toe walls with the foundation, that produces less resistance to percolation than any other path through the foundation material.

If you will see this figure the values that is L_{v1} , L_{v2} , L_{v3} and L_{v4} these are all steep contacts the vertical contacts under distance L_{H1} , L_{H2} and L_{H3} in this figure all are horizontal distances. And all these are called as horizontal plot distances if the slope is less than 45 degree.

So, we generally calculate the weighted creep length the effective seepage length, so, the effective or weighted creep length is estimated as one third of all these horizontal distances plus the sum of the vertical distances. So, it is the sum of all the steep contacts and one third of all the contacts flatter than 45 degree between the headwater on tail water along the contact surface of the drop spillway and foundation. And capital H is the static water table or the upstream side which is mostly causing the seepage below the foundation. So, that is why H is the driving head or driving energy head.

(Refer Slide Time: 19:35)

Lane's Theory for Safe Weighted Creep Ratio (C_w):

$$C_w = \frac{\text{Weighted creep distance}}{\text{Differential water head (H)}}$$

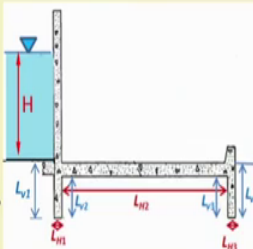

$$C_w = \frac{\sum L_v + \frac{1}{3} \sum L_H}{H}$$

where

- L_H = Horizontal or flat contact distance (slope < 45°).
- L_v = vertical or steep contact distance.
- H = Differential head between headwater & tail-water.

For stability against piping: C_w (calculated) > C_w (Table value)

- Otherwise the depths of cutoff / toe walls have to be increased suitably.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. B. Sahoo, School of Water Resources, IIT KHARAGPUR

So, the length theory for a safe weighted creep ratio is given by C_w . So, C_w equal to weighted creep distance that we have already estimated our summation of L_v . So, L_v equal to L_v1 plus L_v2 plus L_v3 plus L_v4 and 1 third of the horizontal distance. So, that equal to one third of L_h1 plus L_h2 plus L_h3 as shown in this figure divided by capital H, capital H is the driving or static water head which is causing these seepage or the piping failure.

So, for stability against piping generally the calculated C_w value should be greater than the tabular value and the C_w of table value is estimated already computed depending on the different soil type of the foundation material. Otherwise, the depths of cut off or toe walls have to be increased if it is less than the table values, then you have to increase the depth that is L_v1 or L_v2 or L_v3 and L_v4 . So, that the stability against piping failure is achieved.

(Refer Slide Time: 20:57)

Foundation material	C_w (Weighted creep ratio)
Very fine sand and silt	8.5
Fine sand	7.0
Medium sand	6.0
Course sand	5.0
Fine sand (foundation material)	4.0
Medium gravel	3.5
Course gravel including cobbles	3.0
Boulders with some cobbles and gravel	2.5
Soft clay	3.0
Medium clay	2.0

So, these are the different weighted creep ratios of different foundation materials you can see the, for very fine sand and silt which is having more porosity it has a greater C_w value. So, greater C_w value means it is less stable for fine sand is 7, medium sand 6, course sand 5, fine sand 4, medium gravel 3.5, course gravel including cobbles the decouples that is 3, boulders with some cobbles and gravel 2.5, soft clay 3, medium clay 2 then hard clay 1.8 and the least it is very hard clay or hard can that is 1.6 that in that means, it a more stable.

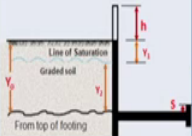

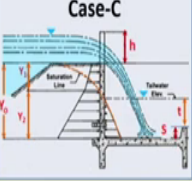

(Refer Slide Time: 21:30)

WEIGHTED CREEP RATIOS OF DIFFERENT MATERIALS

Foundation material	C_w (Weighted creep ratio)
Hard clay	1.8
Very hard clay or hardpan	1.6
Clean gravel	5.0
Clean sand or sand and gravel mixture	6.5
Well-graded mixture of sand, silt, and less than 15% clay	5.5
Well-graded mixture of sand, silt, and more than 15% clay	4.0
Firm clay	2.3

Clean gravel as 5, clean sand or sand and gravel mixture 6.5, well graded mixtures of sand silt and less than 15 percent clay that is your 5.5, it is more than 15 percent clay then it is 4 on 4, and form clay it is 2.3. So, these are the tabular values of C_w so, our values should be greater than this tabular value.

(Refer Slide Time: 22:07)

Backfill condition	Water table	foundation to backfill		position of the saturation line, $Y_s =$		Piping Problem ?	
		type	No flow	Full flow			
Case-A (No backfill)	High	---	None	Y_s	Y_s	Yes	
	Low	---	None	Y_s	Y_s	No	
Case-B 	High	Greater	a	$S + 0.3F$	$t + S + 0.3F$	Yes	
		Greater	b	$S + 0.1F$	$t + S + 0.1F$	Yes

		Equal	b	$s + 0.15F$	$t + s + 0.15F$	Yes	
		Less	a	$s + 0.6F$	$t + s + 0.6F$	Yes	
		Less	b	$s + 0.2F$	$t + s + 0.2F$	Yes	
	Low	Greater	None	0	0	0	No
		Equal	None	0	0	0	No
		Less	a	$s + 0.3F$	$t + s + 0.3F$	No	
		Less	b	$s + 0.1F$	$t + s + 0.1F$	No	

Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

Then, as we have already studied in our previous lecture so, depending on the backfill condition and drainage condition you can design or you can estimate the elevation of the saturation life line Y 2 you can see from this figure case C suppose for example, for case C this Y 2 value you can estimate and that is depending on different water table conditions.

If your water table condition is suppose high and the relative permeability between the foundation to backfill material is equal suppose and drainage condition is a, then known for no flow condition I can get Y to equal to S plus 0.5 F. And this S plus 0.5 F is nothing, but the value of Y 2 and this Y 2 value we can estimate because, it is mostly responsible for estimating how much is my water table depth.

So, the saturation line shows the water table depth in the backfill material. So, that is why during the load computation so, this is Y 2 value is very much important. So, this table will be always referred for all these design calculations of the drop spillway.

(Refer Slide Time: 23:48)

PROBLEM

A drop spillway has to be constructed for a design discharge, $Q= 5.83$ cumec, Length of weir, $L=4$ m, and total drop, $F=2.44$ m. If the depth of the **toewall**, $t_2 = 0.91$ m, find the required depth of cutoff wall (t_1) to ensure safety against piping for the following conditions:

- 1) Pond above structure with no upstream berm against headwall.
- 2) Pond above structure with upstream berm and **type-a drainage**.
- 3) Pond above structure with upstream berm and **type-b drainage**.

Given: $t_2 = 0.91$ m
 $t_1 = ?$

- ✓ Foundation material: well-graded mixture of sand, silt, & clay (Clay content = 20%).
- ✓ Relative permeability of the foundation & fill material = Equal.
- ✓ Water table = High.

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

So, everything will be clear with if you follow a problem you will solve your problem you can see in this problem a drop spillway has to be constructed for a design discharge, Q equal to 5.83, cubic length of weir is 4 meter, total drop is 2.44 meter. If the depth of the toe wall t_2 as shown in this figure equal to 0.91 meter, find the required depth of cut of all t_1 to ensure safety against piping for the following conditions.

So, if there are three conditions given 1 is pond above structure with no upstream bomb against red wall, 2nd is pond ever structure with upstream berm type a drainage and pond above structure with upstream berm type b drainage and the conditions of foundation metal are given.

So, it is well grade a mixture of sand, silt, clay, having clay content 20 percent which is greater than 15 percent relative permeability of the foundation and fill metal equal is equal on water table is high. So, for the foundation metal that is will grade a mixture of sand silt and clay which having clay content greater than 20 percent, you can estimate what is your C W value from this table given table. But for designing this you have to estimate, what is the value of H are shown in this figure. To estimate the value of H naturally you have to estimate what is the value of S?S is nothing, but it is the depth of end silt.

So, as we have studied in the previous classes S can be estimated by using Q and L relationship like by computing the hut the critical depth d_c and d_c you know that not equal to Q square divided by L square g whole to the power 1 by 3. So, once this is estimated so, S will be equal to d_c divided by 2. So, those calculations are can be down in the next slides.

(Refer Slide Time: 25:53)

SOLUTION

Given:
 $Q = 5.83$ cumec, $L = 4$ m
Height of end sill, $S = ?$
 $S = d_c/2$, where d_c = critical flow depth

$$d_c = \left(\frac{Q^2}{gL^2} \right)^{1/3} = \left(\frac{5.83^2}{9.81 \times 4^2} \right)^{1/3} = 0.60 \text{ m}$$

$S = d_c/2 = 0.60/2 = 0.30$ m

$\therefore H = F + S + t_x = 2.44 + 0.30 + 0.25 = 2.99$ m

IIT KHARAGPUR

NPTEL ONLINE
CERTIFICATION COURSES

Dr. B. Sahoo
School of Water Resources

So, for estimating S you have to estimate, what is your d c value? So, here by putting the value of Q and L on z equal 9.81 you can get d c equal to 0.6 meter and S equal to d c by 2 that equal to 0.3 meter.

So, here H can be calculated as shown in this figure that equal to F plus S plus this distance or this height that equal to t x and t x is given as 0.25 meter. So, H will be equal to F plus S plus t x and that equal to 2.44 plus 0.3 plus 0.25 equal to 2.9 and meter, because F is already given that equal to 2.44 meter. So, once H is estimated and we have given t 2 equal to 0.91 meter already. So, to estimate what is my t 1 value by using the lines Creep theory, I can estimate what is mind t 1 value so, that the piping failure would not be happening.

(Refer Slide Time: 27:06)

SOLUTION

✓ For the foundation material: well-graded mixture of sand, silt, & clay (Clay content=20%), $C_w = 4.0$ (From Table)

Material	C_w (Weighted creep ratio)
Clean gravel	5.0
Clean sand or sand and gravel mixture	6.5
Very fine sands and silts	8.5
Well-graded mixture of sand, silt, and less than 15% clay	5.5
Well-graded mixture of sand, silt, and more than 15% clay (foundation material)	4.0
Firm clay	2.3

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. B. Sahoo School of Water Resources IIT KHARAGPUR

Now, for this you have to estimate what is the table value of C W and for the given condition well graded mixture of sand, silt and clay and having clay content 20 percent. So, you can calculate that C W equal to 4.

(Refer Slide Time: 27:24)

SOLUTION:

Using Lane's Creep Theory:

$$C_w H = 2t_1 + (B/3) + 2t_2$$

$$2t_1 = C_w H - B/3 - 2t_2$$

$$= 4H - 4.14/3 - 2 \times 0.91 = 4H - 3.2$$

$$t_1 = 2H - 1.6$$

1. With no upstream berm:

From sketch, $H = 2.99$ m

$$t_1 = 2H - 1.6 = 2 \times 2.99 - 1.6 = 4.40$$
 m

Given: $t_2 = 0.91$ m
 $t_1 = ?$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. B. Sahoo School of Water Resources

So, for all the estimates you can take C_w equal to 4, now using Lane's creep theory you know that $C_w H$ is equal to σL the length of all these horizontal distances divided by 3 plus the summation of all the vertical distances or vertical depths.

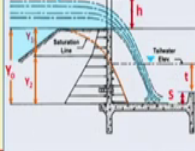

So, in this case the length of vertical distances will be equal to $2t_1$ plus $2t_2$, if you will see this figure this is t_1 and this side also will be equal to t_1 , this is t_2 on this side will be also equal to t_2 . So, $2t_1$ plus $2t_2$ and this B is the horizontal distance, so, it will be divided by 3. So, by solving this you will get $2t_1$ equal to $C_w H$ minus B or B or a 3 minus t_2 and H I have kept here without putting this value so, that we can do later on. So, B equal to 4.14 divided by 3 minus 2 into 0.91 because, t_2 is given as 0.91 , So, we will get $4H$ minus 3.2 now t_1 will equal to $2H$ minus 1.6 .

So, whatever the condition is are given so, depending on that the H value will change. So, for this condition first condition that is with no upstream berm here H is equal to 2.99 meter and directly you can get t_1 equal to $2H$ minus 1.6 . So, H is 2.99 so, we will get it is 4.4 meter, so, this is for the first condition.

(Refer Slide Time: 29:21)

2. With upstream berm and type-a drainage:
 From the given Table, for Backfill Case-C with no flow, Relative permeability of the foundation & fill material = equal; and Water table = high :

$Y_2 = S + 0.5F$

Backfill condition	Water table	Relative permeability of foundation to backfill	Drainage type	Elevation of the saturation line, $Y_2 =$		Piping Problem ?
				No flow	Full flow	
Case-C 	High	Greater	a	$s + 0.4F$	$t + s + 0.4F$	Yes
		Greater	b	$s + 0.1F$	$t + s + 0.1F$	Yes
		Equal	a	$s + 0.5F$	$t + s + 0.5F$	Yes
		Equal	b	$s + 0.15F$	$t + s + 0.15F$	Yes
		Less	a	$s + 0.6F$	$t + s + 0.6F$	Yes
		Less	b	$s + 0.2F$	$t + s + 0.2F$	Yes
Low	Greater	None	None	0	0	No
	Equal	None	None	0	0	No
	Less	a	a	$s + 0.3F$	$t + s + 0.3F$	No
	Less	b	b	$s + 0.1F$	$t + s + 0.1F$	No

Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

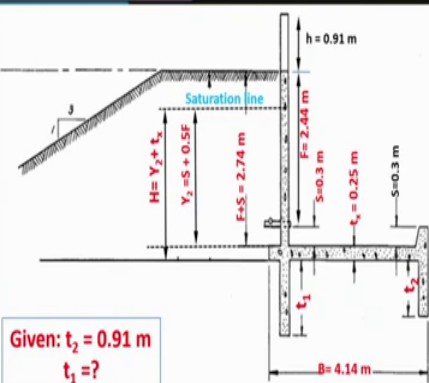

Now, coming to the second condition that is with upstream berm and type a drainage: For type a drainage for the given condition you can find out what is the value of Y_2 , as shown in this figure. So, you can estimate what is the value of Y_2 so, this is my Y_2 . So, here I am getting Y_2 equal to S plus $0.5 F$ that you can estimate from here for no flow condition.

(Refer Slide Time: 29:54)

$Y_2 = S + 0.5F$
 $= 0.3 + 0.5 \times 2.44$
 $= 1.52 \text{ m}$

From sketch:
 $H = Y_2 + t_x = 1.52 + 0.25$
 $= 1.75 \text{ m}$
 $\therefore t_1 = 2H - 1.6$
 $= 2 \times 1.75 - 1.60$
 $= 1.90 \text{ m}$

Given: $t_2 = 0.91 \text{ m}$
 $t_1 = ?$

Dr. B. Sahoo
School of Water Resources
IIT KHARAGPUR

So, once this value is known Y_2 equal to S plus $0.5 F$ that you can use for your subsequent calculations. So, as shown in this figure here H equal to Y_2 equal to S plus

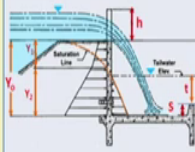

0.5 F, we have already seen that one that Y₂ equal to S plus 0.55 F. So, we can estimate what is the Y₂ value, so, here Y₂ equal to 1.52 meter and this Y₂ is corresponding to that is the depth between the saturation line and the line from this bottom of this say top of this apron so, this is my Y₂ value.

So, that is you can estimate as 1.52 meter and from this case you can get this H equal to Y₂ plus t_x, because these t_x has to be added here then you will get this 1.52 that equal to Y₂ plus 0.25 that equal to 1.75 meter. So, t₁ will be getting that is 2 H minus 1.6 and H equal to 1.75 meter. So, we will get 1.9 meter. So, my t₁ value is 1.9 meter.

(Refer Slide Time: 31:16)

3. With upstream berm and type-b drainage:
 From the given Table, for Backfill Case-C with no flow, Relative permeability of the foundation & fill material = equal; and Water table = high :

$Y_2 = S + 0.15F$

Backfill condition	Water table	Relative permeability of foundation to backfill	Drainage type	Elevation of the saturation line, $Y_2 =$		Piping Problem ?
				No flow	Full flow	
 <p>Case-C</p>	High	Greater	a	$S + 0.4F$	$t + s + 0.4F$	Yes
		Greater	b	$S + 0.1F$	$t + s + 0.1F$	Yes
		Equal	a	$S + 0.5F$	$t + s + 0.5F$	Yes
		Equal	b	$S + 0.15F$	$t + s + 0.15F$	Yes
		Less	a	$S + 0.6F$	$t + s + 0.6F$	Yes
		Less	b	$S + 0.2F$	$t + s + 0.2F$	Yes
Low	Greater	None	None	0	0	No
	Equal	None	None	0	0	No
	Less	a	$S + 0.3F$	$t + s + 0.3F$	No	
	Less	b	$S + 0.1F$	$t + s + 0.1F$	No	

Dr. B. Sahoo
 School of Water Resources
 IIT KHARAGPUR

Similarly, you can do for the 3rd case, so, for the 3rd case it is type b drainage, for type b drainage similarly can selects what is my Y₂ value. In this case you can see the Y₂ value is equal to S plus 0.15 F that you can see from this table. So, this is the distance from this bottom surface to the saturation line. So, once Y₂ is known so, by using this you can estimate what is my H value.

(Refer Slide Time: 31:53)

$$Y_2 = S + 0.15F$$

$$= 0.3 + 0.15 \times 2.44$$

$$= 0.67 \text{ m}$$

From sketch, $H = Y_2 + t_x$
 $= 0.67 + 0.25 = 0.92 \text{ m}$

$\therefore t_1 = 2H - 1.6$
 $= 2 \times 0.92 - 1.6$
 $= 1.84 - 1.6 = 0.24 \text{ m}$

Recommended: $t_1 = 1.2 \text{ m}$
 (minimum depth of cutoff wall should be 1.2 m)

Given: $t_2 = 0.91 \text{ m}$
 $t_1 = ?$

✓ This example indicates the effect of the earth berm and a good drainage type.

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES | Dr. B. Sahoo School of Water Resources

So, for this first I have to estimate what is my Y_2 that equal to $S + 0.15F$ that I can compute here. So, S equal to 0.3 and F equal to 2.44. So, I can get Y_2 equal to 0.67 meter, on from the sketch you can get H equal to $Y_2 + t_x$ and Y_2 equal to 0.67 plus t_x equal to 0.25., so, we are getting 0.92 meter.

So, once H is known this H is known, you can estimate what is t_1 that equal $2H - 1.6$. So, by putting the values of h and that is 1.6 here, so, we will get t_1 equal to 0.24 meter. You know that the minimum depth of this cutoff wall should be 1.2 meter, but this value is 0.24 meter which is much below than that of 1.2 meter. So, for this case you can recommend the minimum value that equal to 1.2 meter so, your minimum t_1 value equal to 1.2 meter.

So, if you are providing a cut off wall of depth 1.2 meter, then it is c code from the piping failure. So, this example shows that, what are the effect of different earth wall and the drainage condition? It can be drainage condition a, it can be drainage condition b and it can be no flow and because of that how the cutoff wall depth is changing or it can be optimized so, that there would not be any piping failure.

So, from this lecture we summarized that what are the contact pressures, what is piping failure, what are the main causes of piping failure, and to withstand against the piping failure, how will design our depth of cutoff wall and what is the optimized depth of cut off wall and we discussed about the overturning depending on the uplift pressure and the

vertical pressure loads at what is my z ? That is the or the eccentricity according to that whether it will be overturning or not ok.

So, this completes our lectures here and then in the next class we will be discussing about how the contacts pressures will be estimated by using the line of creep theory. So, we will end our lecture here.

Thank you very much.
