**Use of ML for Portable Proximal Soil and Crop Sensors**

(Refer Slide Time: 00:22)

Welcome friends to this week 6 of lectures for this NPTEL online certification course of Machine Learning for Soil and Crop Management. And this will be the first lecture of week 6, lecture number 26. And in this lecture, we are going to cover some important aspects. In this week, we are going to cover some of the important portable proximal sensors and how we have used them along with the machine learning approaches for different types of soil survey and soil property prediction as well as crop characterization.

So, in our previous couple of weeks, we have discussed the basics of machine learning and deep learning and the basics of multivariate data analytics we have seen, different aspects of sub classification as well as regression. And in our previous week, we have discussed about the diffuse reflectance spectroscopy, the details as well as how spectrally you can characterize soil as well as rock. So, today, we are going to start discussing about the other portable proximal sensors.

(Refer Slide Time: 02:00)

**CONCEPTS COVERED**

- Historical and Modern Soil Survey
- Proximal Sensors
- Portable XRF (PXRF)
- Soil PXRF Applications

The slide features a light green background with a dark blue header and footer. A decorative graphic on the right side consists of a blue triangle, a green triangle, and a dark blue semi-circle. Logos for IIT Bombay and NPTEL are visible in the bottom right corner.

So, these are the concepts which we are going to cover. First of all, I will give you a very brief overview of historical and modern soil survey and why we now need the application of advanced sensors. And then, we are going to talk about the proximal cell sensors or proximal sensors and their classification. Then, we will start with the Portable XRF for Portable x-ray fluorescence spectrometer. And then, we are going to see some Soil PXRF Applications.

(Refer Slide Time: 02:51)

**KEYWORDS**

- Proximal sensors
- SSNM
- PXRF
- Primary X-ray
- Fluorescence

The slide features a light green background with a dark blue header and footer. A decorative graphic on the right side consists of a blue triangle, a green triangle, and a dark blue semi-circle. Logos for IIT Bombay and NPTEL are visible in the bottom right corner. A small video inset in the bottom right shows a man speaking.

These are the some of the keywords which we are going to discuss today. One is Proximal sensors then SSNM or Site-Specific Nutrient Management then PXRF, primary x-ray and Fluorescence.

(Refer Slide Time: 03:08)

## HISTORICAL SURVEY

U. S. DEPARTMENT OF AGRICULTURE  
BUREAU OF SOILS

RECONNOISSANCE SOIL SURVEY  
OF SOUTH TEXAS.

BY  
GEORGE S. COFFEY  
AND PARTY.

(Advance Sheet—Field Operations of the Bureau of Soils, 1922.)

WASHINGTON:  
GOVERNMENT PRINTING OFFICE,  
1916.

- Since the earliest days of soil survey, geology has strongly influenced the discipline
- Mapped soils based on
  - Geologic formations
  - Landforms
  - Lithology

So, you know that for soil science, the historical survey of soil started long back by US Department of Agriculture. And they relied on, initially they relied on reconnaissance soil survey. And since the earliest days of soil survey, geology has strongly influenced the discipline. And at the time, the soils were mapped based on geologic formation, landforms and lithologic. As you can see, this is a picture of reconnaissance soil survey in Texas in 1922. So, the history of soil survey started with the reconnaissance soil survey, where geology played a major role for mapping of soil.

(Refer Slide Time: 04:11)

## HISTORICAL SURVEY

- Curtis Marbut's historical *Normal Soil* concept identified two major types of soils:
  - **Pedocals:**
    - Containing large amounts of  $\text{CaCO}_3$
    - Mainly found in the western US
  - **Pedalfers:**
    - Containing large amounts of Fe and Al
    - Mainly found in the eastern US

Bkkm laminar cap in West Texas; Weindorf

Now, Curtis Marbut the scientist, he first gave this normal soil concept which identified two major types of soil, one is Pedocals and another is Pedalfers. So, Pedocals are the types of

soil which contain large amounts of calcium carbonate and mainly found in the western United States.

And in case of Pedalfers, it contains a large amount of iron and aluminium and mainly found in the Eastern US. And also, as the name suggests calcs, which contains ca that means it contains calcium carbonate whereas in case of Pedalfers, which is alfe that means aluminium and iron dominance is there.

(Refer Slide Time: 05:14)

**HISTORICAL SURVEY**

- 1950s-1960s saw rapid advances in soil chemistry, soil physics, soil biology, soil mineralogy, etc.
  - Drove a shift from qualitative to quantitative soil survey
- By the 1960's Guy Smith was commissioned to develop a new system of soil classification based on quantifiable data and discrete classes

Now, in 1950, during 1950s to 60s soil science has saw rapid advances in soil chemistry, soil physics, soil biology and soil mineralogy, etcetera, the disciplines. Which drove a shift from qualitative to quantitative soil science. So, earlier scientists mainly resort to qualitative soil survey, but with the advent of these some disciplines of soil science, like soil chemistry, soil physics, soil biology, soil mineralogy, it drove a shift from qualitative to quantitative soil survey.

People were more interested in quantitative description of soil properties. By the 1960s Guy Smith was commissioned to develop a new system of soil classification based on quantifiable data and discrete classes. So, that marks a paradigm shift as far as the soil survey and soil characterization are concerned.

(Refer Slide Time: 06:24)

**MODERN SURVEY**

- 1990s – present
  - Global positioning system (GPS) receivers were used to notate exact locations of descriptions, field notes, etc.
  - Proximal and remotely sensed data represent new collection tools capable of providing large amounts of data at minimal cost *and reduced labor requirements*
    - Infrared satellite imagery
    - **Visible and near infrared diffuse reflectance spectroscopy**
    - Ground penetrating radar
    - Electromagnetic induction
    - **Field portable x-ray fluorescence spectrometry**
    - In-situ soil sensor arrays connected to dataloggers measure water and gas movement through the soil in real-time in relation to climate observations (rainfall, temperature, etc.)

So, from 1990s to present time, the Global Positioning System receivers were used to notate exact location of descriptions, field notes, etcetera. And proximal and remotely sensed data represent a collection of tools capable of providing large amount of data at minimal cost and reduced labor requirements.

There are several types of sensors people are using nowadays, like infrared satellite imagery they are using, visible near infrared diffuse reflectance spectroscopy or DRS, we have discussed the details in our previous week, that ground penetrating radar, electromagnetic induction, field portable x-ray fluorescence spectrometry, then in situ soil sensors that is connected to data loggers and then these data loggers can measure water and gas movement to the soil of real time in relation to climate observations.

So, there are different types of sensors are being used to generate the quantity information instead of qualitative information that gives this soil survey a huge leap and also more chance for exploiting or the machine learning and deep learning-based algorithms for soil characterization and answering some of the unanswered question in the soil science domain and crop size domain.

(Refer Slide Time: 08:11)

## WHAT IS LIMITING THE PRODUCTIVITY OF THIS SOIL?

pH? Salinity? Soil texture? Soil cation exchange capacity? Organic matter? Pollution?

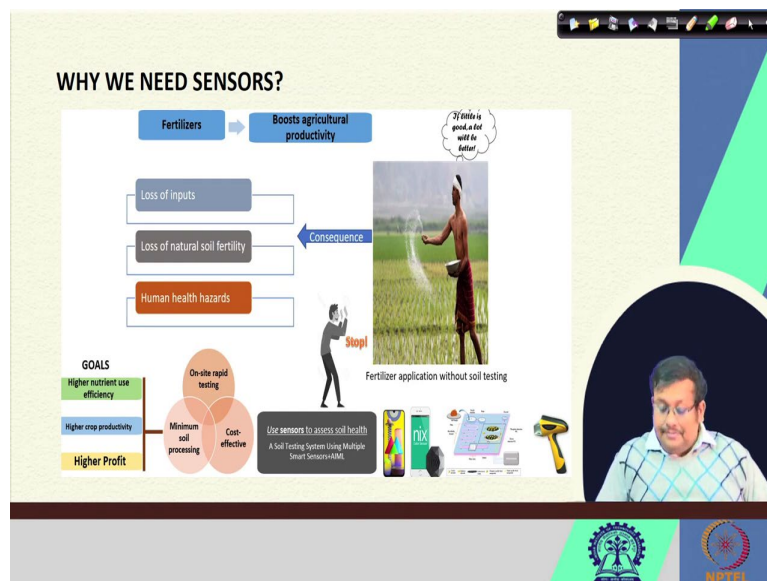

Now, if we take a look at this barren surface where the crops are very much scarce. So, what is the limiting productivity in this soil? The first question comes to our mind: what is the limiting productivity of this soil, is this due to pH, is this due to salinity, is this due to soil textural variation, is this due to unfavourable cation exchange capacity, is this due to low organic matter, is this due to pollution, we never know.

So, the only way of accessing or answering this question is to take the soil samples, bring them into the lab, analyze them, and after the analysis, which is time-consuming, we can tell, okay, this is the major limiting factor. But think about some alternative where we are using some sensors which we can directly use in the field to answer these queries.

This will give us more information for answering this question, which is the most important limiting factor of this soil. So, here you can see this PXR sensor is placed in the soil, and using this PXR extracted data along with some machine learning and statistical application, it is now possible to identify what is the major cause of this situation in the soil.

(Refer Slide Time: 10:17)

So, another perspective of using this sensor is to boost the agricultural productivity. You know that fertilizers we generally use in the field for boosting the agricultural productivity and most of the farmers they generally think since they do not have the access to the traditional soil testing services, they really think that if little is good, that lot will be better for increasing the agricultural productivity because to increase the you know, it because of productivity fertilizer is one of the major inputs.

However, due to these indiscriminate. So, as a result of that, they generally apply these fertilizers in a blanket fashion. And due to this blanket application of these fertilizers, there are three major problems one is they are losing the inputs, and due to the application of these chemical fertilizers, there is loss of natural soil fertility and the also creates human health hazards because these are synthetic chemicals.

And this nitrogenous fertilizer application, these nitrates can go to the groundwater and then contaminate the groundwater which can cause human health hazard. So, to stop this fertilizer application, without soil testing, it is important that we should take the help of some of the smart sensors which are available off the shelf and we can use them for rapid measurement of soil properties use them as auxiliary tools along with the standard soil testing services.

So, we need to use this type of sensors to assess the soil health along with AIML tools are artificial intelligence machine learning tools. And the three major objectives are for onsite rapid testing, and then to maintain the cost effectiveness of the total analysis. And thirdly, is to minimally processed the soil.

And finally, the use of these proximal sensors and cheap soil sensors or cost effective soil sensors are first to increase the utility use efficiency because we are not now, we are giving the fertilizer based on the need of the crop we are not applying the fertilizer in a blanket fashion then we are improving the crop productivity and finally and most importantly, we are improving we are increasing the profit of the farmers because unless we can increase the profit of the farmers, they will not be attracted to these type of advanced sensors.

(Refer Slide Time: 13:28)

Now, if we consider the conceptual framework of the site-specific nutrient management, which is a very important word nowadays in the agricultural domain, because site specific nutrient management will help you to reduce the fertilizer consumption and to increase the fertility. So, you can see that how this smart soil sensing framework can help in site specific nutrient management.

So, for this smart soil sensing framework, the ultimate end product is the yield map, which we can create using different sensors, we have already discussed about the diffuse reflectance spectroscopy and apart from that portable XRF is there and then on the go soil sensor is there, the mobile soil testing lab then optical sensors and smartphone images, we could use all of them to develop these yield map and ultimately these yield map will be considered as an input for variable rate application.

Now, this variable rate application will also take the help of this decision-making system. So, this decision-making system is directly linked with this yield map and also these decision-making system takes the help of remote sensing and also crop canopy sensor-based measurement, UAV based measurement and also smartphone images.

So, in combination with the yield map and also remote sensing imagery, crop canopy sensor measurement, UAV imagery and smartphone images, we can make a decision-making system and based on this decision-making system, it is now possible to develop to, it is now possible to use this variable rate applicator for site specific nutrient management. So, you can see that how these different components are linked together and how these are interrelated.

And in each of these application for example, optical sensor-based soil property mapping, then smartphone images, then portable XRF, then DRS, and then remote sensing, crop canopy sensor-based modeling, UAV, smartphone images, you can see all of them takes the help of artificial intelligence and machine learning applications. We are going to discuss it this week, in the coming weeks. So, this gives you a conceptual framework of the site-specific nutrient management.

(Refer Slide Time: 16:24)

**PROXIMAL SOIL SENSORS**

*Proximal soil sensors are the ground-based sensors used in agriculture to gather information about different soil properties by obtaining signals with direct contact with soil samples or from a distance within 2 m*

(Viscarra Rossel et al., 2011)

The slide features a video inset of a man in a blue and white checkered shirt speaking. At the bottom, there are logos for IIT Bombay and NPTEL.

And let us see what is the definition of proximal soil sensors. So, according to Viscarra Rossel et al in 2011 he define these proximal soil sensors as these are the sensors, these are the ground-based sensors used in agriculture to gather information about different soil properties by obtaining signals with direct contact with soil samples or from a distance within 2 meter. So, these sensors, we generally keep them in contact with the soil or within a distance within 2 meter. So, that is why they are called proximal soil sensors.

(Refer Slide Time: 17:09)

Now, if we see the classification of the proximal soil sensors based on their mode of operation, we can classify them into 5 categories. First one is the one which is the first category basis reflected radiation. For example, in this category, diffuse reflectance spectroscopy, then Nix Pro sensor, then camera images, smartphone images, digital images, they will come.

Secondly, so, they are helpful for measurement of soil organic matter, total organic carbon, total nitrogen, soil, colour, texture and moisture because they showed the colour variation that they are colour sensitive, proximal soil reflectors. Then, the second category measures incoming radiation from the soil in this category PIXRF, gamma spectrometry and laser induced breakdown spectroscopy will be there and they can measure in soil element, soil texture, pH, salinity, volumetric moisture.

In the third category, these sensors measure backscattered electromagnetic waves or temporal propagation of electromagnetic waves. The examples of these sensors are EM or electromagnetic induction, then ground penetrating radar, then time domain reflectometry or TDR and frequency domain reflectometry these sensors can measure volumetric moisture content, salinity, soil texture and structure.

The fourth category measured the horizontal or vertical soil strength example penetrometer they can measure soil strength and bulk density. And the fifth category measures electrochemical properties examples are ion selective electrodes and ion sensitive field effect transistor (I) (19:01). So, they are helpful for measurement of pH, salinity and ion activities.

So, we can see that there are different categories of proximal soil sensors and based on their mode of operation and they are categorized and they can address or they can measure a set of soil properties, they cannot predict or characterize all the soil properties but a set of soil properties.

(Refer Slide Time: 19:38)

**PXRF (or pXRF or HH-XRF)**

- **Portable X-ray Fluorescence Spectrometry**
- **Advantages:**
  - Field portability ✓
  - No consumables ✓
  - Non-destructive ✓
  - Multi-elemental analysis (providing simultaneous analysis of 20-30 elements) ✓
- **Parameters:**
  - Soil pH, EC, CEC, P, K, Ca, Mg, S, Micronutrients, Gypsum, %BS, Heavy metals, permafrost pH, LULC, Parent material, Profile horizonation, Geochemistry, Compost EC, Compost CEC, Water heavy metals, Leaf elements

60-90

The slide features a handheld PXRF device, a detailed diagram of its internal components including a CPU, digital signal processor, X-ray source, and detectors, and a video inset of a speaker. Logos for IIT Bombay and NPTI are visible at the bottom.

So, let us move ahead and see, we can start with the portable XRF, PXRF, sometimes we call it PXRF, sometimes people call it small pXRF, sometime we call it HH-XRF or handheld XRF. So, you can see these terms very frequently. Remember that these terms are synonymous, so, PXRF, small pXRF and HH-XRF these are same term. So, we will be using these PXRF in this course.

So, the PXRF stands for the portable x-ray fluorescence spectrometry, the technique is known as portable x-ray fluorescence spectrometry and the instrument is known as portable x-ray fluorescence spectrometer. This is a portable x-ray fluorescence spectrometer, you can see here it is a handgun type of instrument and this instrument is field portable, this does not require any consumable, it can measure the soil properties without any chemical treatment, it is non-destructive that means it does not destroy the soil samples during its analysis.

And it helps for multi elemental analysis and provides the simultaneous analysis of 20 to 30 elements starting from Magnesium to Uranium. So, this is very lightweight, earlier versions were around 1.5 kg. Now, the latest versions are lighter than that, almost 1 kilo of weight at this is very fill portable rugged, and they can be taken into the field for measurement of soil properties.

So, this instrument you can devise, you could go, you can take it to the, in the field or you can use the with the lab also and you can touch the nose of this instrument to the bare soil surface and then you can press the trigger and within 60 to 90 seconds, it will give you the reading of the total elemental content, within 60 to 90 seconds and it will give you the total elemental content from Magnesia to Uranium.

So, using these elemental contents scientists have proved the utility of this instrument for measurement of soil pH, electrical conductivity, cationation capacity, all the macro and micronutrients, gypsum, percent-based saturation, heavy metals, pollution, permafrost pH, land use land cover classification, parent material, profile horization, geochemistry, compost EC and CEC, then water heavy metals, and leaf elements.

So, you can see this instrument has been used extensively it both soil and crop as well as in the water for measurement of multiple properties. So, this is the internal construction of this instrument, we are going to talk about this principle more in our coming slides, but this instrument has changed the concept of soil testing drastically in the last 10 years. And in Western countries now, it has been utilized as one of the major, one of the approved methods of soil testing.

(Refer Slide Time: 23:06)

### XRF WORKING PRINCIPLE

- PXRF quantifies Mg to U
- The primary X-ray radiation is produced in a vacuum-tight tube containing a cathode, which is the source of electrons with a high accelerating voltage supplied by a generator that works in a range of 20–60 kV, and an anode (metal target)
- When the electrons produced by the cathode collide with the metal target, X-rays are produced.
- The metal of the anode is usually selected among elements with high melting point and atomic number able to produce high intensity, primary X-ray radiation such as Rh, Mo, W, Cr, and others
- Since the kinetic energy with which the anode is hit is converted into heat, in the past a water circuit was used to avoid melting of the anode and overheating of the entire system, while newer instruments are air-cooled

The diagram illustrates the XRF working principle. It shows a vacuum-tight tube containing an anode (metal target) and a cathode. An electron beam is directed from the cathode to the anode. This collision produces primary X-rays. These X-rays strike the sample surface, causing secondary X-rays and ejected electrons. A detector captures the secondary X-rays. The diagram also shows a cooling system and a metal target. The sample surface is shown with various elements (Mg, Si, Al, Fe, Ca, K, Na, S, P) and their respective energy levels. The diagram is labeled 'XRF WORKING PRINCIPLE' and includes a citation 'Silva et al. (2021)'.

So, if we see the working principle of this instrument, this instrument basically works, the working principle of PXRF is same as x-ray fluorescence. Now, basically what happens in this instrument there is a primary x-ray beam. So, this primary x-radiation is produced in a vacuum tight tube containing a cathode, here is the cathode which is the source of electrons

with a high accelerating voltage supplied by a generator that works in a range of 20 to 60 kilo volt.

And an anode which is the metal target, this is an anode which is a metal target. So, when the electrons which are produced by this cathode collide with this anode, then this is a metal target or anode, these x-rays will be produced which is known as the primary x-rays. So, the metal of the anode is usually, so this anode is metal.

So, this metal of these anode is selected among the elements with high melting point and atomic number able to produce high intensity primary x-ray radiation such as, so generally the metals we are used are Rh, Mo, W, Cr and other. So, generally they are used for this anode. And this is the kinetic energy with which the anode is heat is converted into heat the past water circuit was used to avoid the melting of the anode and overheating of the entire system while newer system are air cooled system. So, this is how this primary x-ray beam is generated.

(Refer Slide Time: 24:59)

**XRF WORKING PRINCIPLE**

- Primary X-rays pass through a filter (also called window)
- The wavelengths comprising the secondary fluoresced X-ray radiation are identified and measured by a detector (e.g., gas-filled, scintillation counters, solid-state), which converts individual photon energy into pulses of electric energy
- Since each chemical element has characteristic X-ray spectral lines, and their intensity is related to the amount of the element, it is therefore possible to ascribe X-ray spectra to their own elements, and assess their abundance in the sample

Silva et al. (2021)

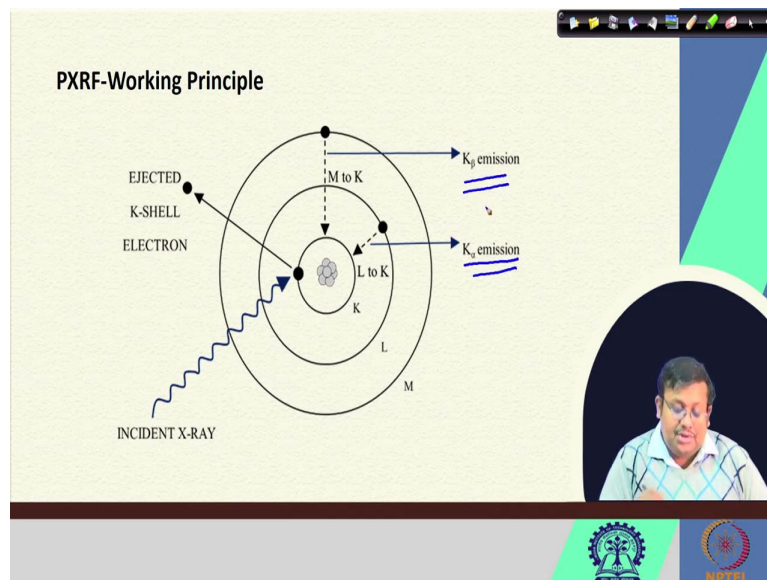

So, in the next step this primary x-ray beam generally goes through a filter also known as this window and this primary x-ray beam interacts with the electrons which are there in the lower orbitals of the atoms and then ejecting them and these atoms get energized and then they eject from these lower orbitals creating an electron hole. And the next step, the electrons from the higher orbital cascade down to fill up these voids.

And when they try to cascade down to these to fill up these voids, they will release the secondary x-rays and then they are known as the fluorescence and in the terms of photons,

and they will be detected by the detector. So, the wavelengths comprising the secondary fluorescence x-ray radiation and are identified and measured by these detectors, which are either gas field scintillation counters or solid state.

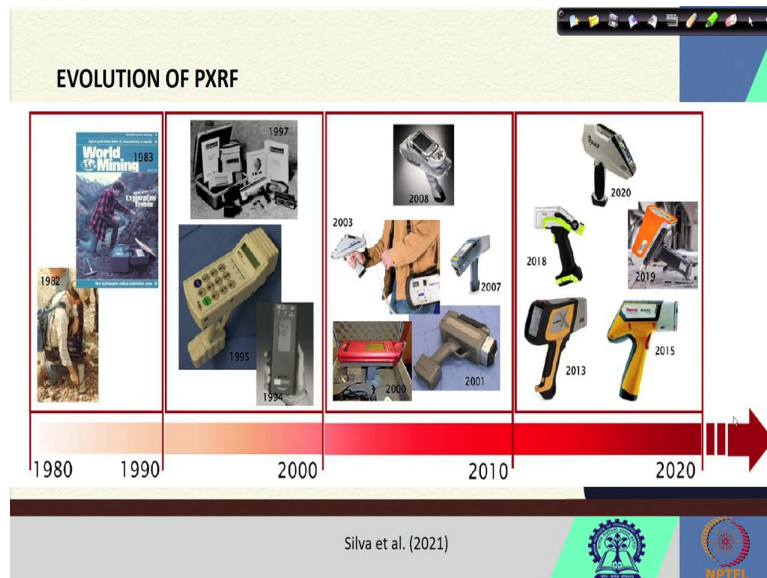

Nowadays, most of the detectors are solid state which converts this individual photon energy into pulses of electrical energy. Now, since each chemical element has characteristic x-ray spectral line and their intensity is related to the amount of the element, it is therefore, possible to ascribe x-ray spectra to their own elements and access that abundance in the sample. So, this is how the x-ray fluorescence technology works and the same technology works in the portable x-ray also.

(Refer Slide Time: 26:43)

Now, depending on that transition, depending on the transition of these of these electrons from the higher orbitals to lower orbitals, we can see different types of naming of this emission. For example, when the electrons move from this L orbital to K orbital, then we turn with K alpha emission when the transition occurs from M orbital to K orbital then it is known as the K beta emission. And so, it depends on from where this transition is occurring. Ultimately, we are naming them as alpha emission or beta emission.

(Refer Slide Time: 27:35)

Now, if we see the evolution of PXRF, it has been used since 1980s. But at the time the instrument was heavy, heavy and with the passing of time with the advancement of technologies, these technologies have been evolved drastically and with the advent of the solid-state detectors, we have seen a drastic change in the technology, a drastic change is the PXRF technology which helped the scientists for better characterization.

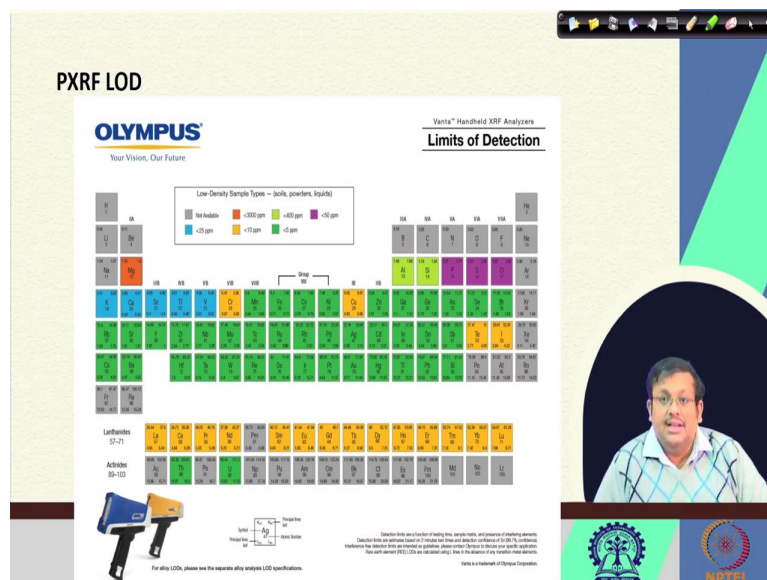

And so, there are different types of companies, several companies who are producing this instrument nowadays, and they are available in the market. And so ultimately, we have seen there has been a drastic change in this technology, earlier instruments were heavy and latest instruments are lightweight, and they are more rugged and they are proof to the drop test. The new versions of Olympus instruments for example, they are proof to the drop tests. So, if you drop them in the field that will not create any problem for this type of sensors. So, you can see that there has been tremendous improvement in this type of sensors.

(Refer Slide Time: 29:30)

And this instrument can be used both in situ as well as ex situ and as you can see scientists are using them in the field directly touching the instrument in the soil profile to define the soil profile. Also, they have been used in the lab. Of course, when you use them in the lab, you can control the variability in the soil. However, for soil application also there are some prescribed steps which you can follow for reducing the heterogeneity in the measurement.

(Refer Slide Time: 30:17)

So, the limit of detection, if you can see this is the limit of detection of earlier version of Vanta PXRF Analyzers produced by Olympus and you can see that most of the heavy elements are having the LOD of less than 5 PPM and only aluminium and Si as they have the LOD of less than 400 PPM.

And some of the elements like phosphorus, sulphur and chlorine they have the limit of detection of less than 50 PPM. So, nowadays the instruments with lower limit of detection are now available, which can give you the more accurate results and they can quantify the minute amount of these presence of these elements in the soil surface.

(Refer Slide Time: 31:14)

**REFERENCE METHODS FOR PXRF SOIL APPLICATIONS**

**METHOD 6200**  
FIELD PORTABLE X-RAY FLUORESCENCE SPECTROMETRY FOR THE DETERMINATION OF ELEMENTAL CONCENTRATIONS IN SOIL AND SEDIMENT

6200 - 1 February 2007

**USDA**  
United States Department of Agriculture  
Natural Resources Conservation Service  
National Soil Survey Center  
Kelllogg Soil Survey Laboratory  
Issued 2014

**Soil Survey Field and Laboratory Methods Manual**  
Soil Survey Investigations Report No. 51  
Version 2

**Portable X-ray Fluorescence Spectrometry Analysis of Soils**  
David C. Weindorf and Formanite Charanthy

**TABLE OF ELEMENTAL CONCENTRATIONS**

Element	CAS Registry No.
Antimony (Sb)	7440-36-0
Arsenic (As)	7440-38-0
Barium (Ba)	7440-39-0
Calcium (Ca)	7440-49-9
Chromium (Cr)	7440-47-3
Cobalt (Co)	7440-48-4
Copper (Cu)	7440-50-8
Lead (Pb)	7439-92-1
Manganese (Mn)	7439-96-4
Nickel (Ni)	7440-02-0
Selenium (Se)	7782-49-2
Silver (Ag)	7440-22-4
Thallium (Tl)	7440-28-0
Tin (Sn)	7440-31-1

So, there are different reference methods for portable XRF soil application. One is given by the US EPA as you can see the first one which is called the method 6200. The second one is given by USDA, United States Department of Agriculture NRCS. And the third one is produced by myself and Professor David Weindorf of Texas Tech University, now he is at the Central Michigan University.

So, we have produced this portable x-ray fluorescence spectrometry analysis of soil as a method of soil analysis published by Soil Science Society of America. So, these three are largely known standard difference methods for PXRF soil applications.

(Refer Slide Time: 32:11)

**REFERENCES**

So, these are the references which I have used. So, guys, in a nutshell, we have seen that why we need these advanced sensors nowadays because these advanced sensors are helpful for both soil survey as well as to reduce the application of chemical fertilizer in the field and to maintain the environmental sustainability and to increase the profitability of the farmers, to increase the productivity of the field.

And there are this smart solid sensing framework using different types of sensors optical sensors, PXRF sensors, spectral sensors can help in developing the yield map which can be used as an input for site specific nutrient management. Of course, along with several other sensors like satellite imagery, then crop canopy sensors, and all these operations are interrelated and takes the help all these operations, take the help of the machine learning and deep learning application to accomplish their objectives.

And we have seen the broad classification of the proximal sensors based on their mode of operation. And we have also seen, we have also started discussing the portable XRF we have seen the basic working principle, and what are the benefits of this instrument and in the next class, in the next session, we will be starting discussing how this application of PXRF started in the domain of soil and how evolution of different statistical methods happened while using this PXRF for soil and crop characterization.

So, I hope that you have learned something new. And let us up some of these discussions you will find in my other NPTEL course, soil science and technology where I briefly touched these PXRF. But here we will be discussing their application in details along with the mathematical explanations.

And we will be, in the next lecture, we will be discussing how we have started with the basic statistical tools and then we move towards machine learning tools for exploring the soil properties using the portable XRF based elemental data from soil. So, guys, thank you. Let us meet in our next lecture to start from here and I will show you more application of PXRF for soil and crop characterization along with the different machine learning applications. Thank you.
