

FOOD SCIENCE AND TECHNOLOGY

Lecture02

Lecture 2: Food Production and Processing Challenges

Hello everyone, Namaskar. Now, in this second lecture, we will discuss the food production and processing challenges.

The concepts which will be covered in this lecture include population growth and food demand, the impact of global warming on food production, limited resource management for food production, food security and production methods,

quantitative and qualitative losses in the food supply chain, and management of food losses.

Now, let's talk about global food challenges. You know, food is one of the basic needs of humans. However, providing proper food for everyone is still a challenge. Some of the challenges in sustainable food supply are population growth and increased food demand,

Introduction to global food challenges

- ❑ Food is one of the basic need of human, however getting proper food is still a challenge.
- ❑ Some of the challenges in the sustainable food supply are
 - ✓ Population growth and increase in food demand
 - ✓ Food production and yield
 - ✓ Global warming and subsequent climate change
 - ✓ Food losses
 - ✓ Need of sustainable food processing techniques
- ❑ Current lecture discusses the alarming issues involved in these aspects followed by the probable solutions.
- ❑ It also discusses importance and implementation of supply chain management followed by application of innovative techniques.

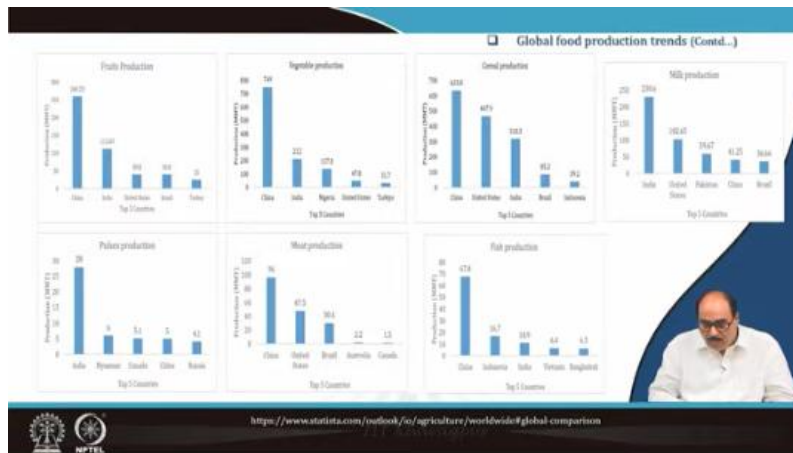

NPTEL

food production and yield, global warming and subsequent climate change, huge losses in food production both during the pre-harvest and post-harvest, and also at the consumer end and finally, the need for sustainable food processing techniques. So, this lecture discusses the alarming issues involved in these aspects, followed by probable solutions. It will also discuss the importance and implementation of supply chain management, followed by the application of innovative technologies.

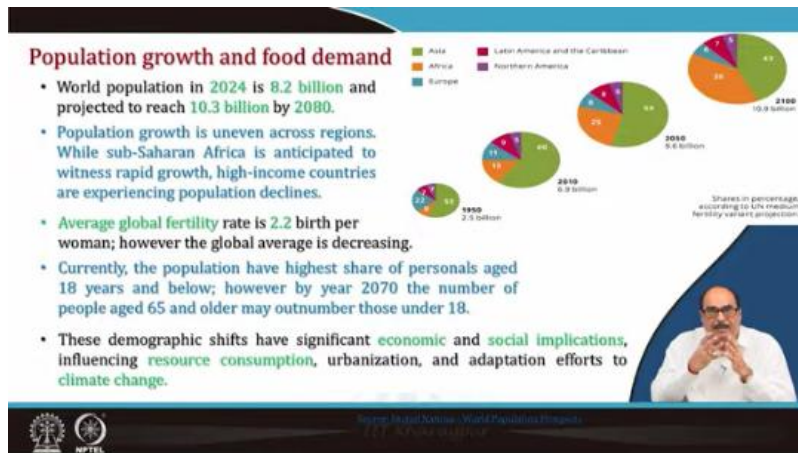

So, here in the first lecture, I provided some data on food production. If you see the global food production trends from 1961 to 2023, You can see the land utilization; almost the cultivable, agricultural land has either remained constant or is decreasing sometimes. So, there is not much increase in agricultural land or land for cultivation. You see the other things like population has increased very significantly. And the increase is also there in the

cereal yield, cereal production, etc. and it is even 0 to up to 250% over these years. Similarly, if you can see the fruits and vegetable trends, the trend in banana production has increased. But in some of the fruits like oranges, apples, etc., or oranges and grapes, etc. The production rate has not increased very much from 2000 to 2022; the data is there. Similarly, in the vegetables, some vegetables like tomatoes, etc., there has been an increase in the rate. But the rate of increase for some vegetables like eggplants, etc., has been less. Similarly, in fish, pig, beef, poultry, sheep, goat, etc. The trend of the production in million tons is given here. This picture shows the trend of milk production as well as prices. You see the production has been, it is global data; it has been increasing significantly throughout. However, the prices fluctuate; sometimes, there is an increase in the milk price, and sometimes, there is a decrease, and it is best known to the regions of the countries. There are various factors for this, so in this case, global production is continuing again.

Here, we have shown that the major top five producers, so in the case of fruit production, China, India, the United States, Brazil, and Turkey are the major top five producers. India produces 112.63 million tons of food annually. In the vegetables also, the same scenario is almost there. India is second after China in vegetable production. In cereal production, India comes in third place. First place is China, and second place is the United States, with 633.8 million tons and 467.9 million tons produced, respectively. India produces approximately 318.3 million tons of cereals. Similarly, in milk production, India is the number one producer, followed by the United States, Pakistan, China, and Brazil, which are the top five milk producers worldwide. In pulses, India is again the major producer, with an annual production of 28 million tons. Myanmar, Canada, China, and Russia are the other four producers. In meat production, India does not rank among the top five producers. The top five producers are China, the United States, Brazil, Australia, and Canada. In fish production, India ranks third, with an annual production of 10.9 MMT of fish. You will

notice that in all these commodities, China is number one, and Indonesia also holds a significant position in some of these commodities. Population growth and food demand are the major challenges in meeting the food needs of people. Food security is threatened by population growth, and you can see here that from 1950 the world population was about 2.5 billion, and by 2100, the population is expected to grow to about 10.9 billion.

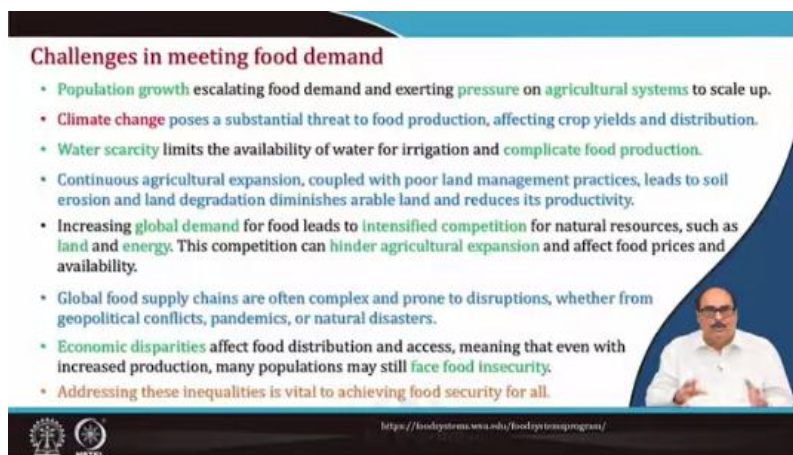

Population growth is uneven across regions. While sub-Saharan Africa is anticipated to witness rapid growth, high-income countries are experiencing population decline. The average global fertility rate is 2.2 births per woman. However, the global average is decreasing. Currently, the population has the highest share of personnel aged 18 years and below. However, it is predicted that by the year 2070, the number of people aged 65 and older may outnumber those under 18. These demographic shifts have significant economic and social implications, influencing resource consumption, urbanization, and adaptation efforts to climate change. You see that even here in Asia, the population by 2050 will be about 54% of the population followed by 25% in Africa, and then other countries, with 88% in Latin America. Europe has about 5%, North America similarly, and the trend is growing.

So if you look at the food demand and consumption patterns, obviously, the total global food demand is expected to increase by 35% to 56% between 2010 and 2050. The population at risk of hunger is expected to change by minus 91% to plus 8%. If climate change is taken into account, the ranges change slightly to plus 30% to plus 62% for total food demand and minus 91% to plus 30% for the population at risk of hunger. So you see here these global malnourishment conditions in African regions, and also in Indian regions is more than 75% and this is an alarming situation for Africa as well as in India.

This graph also shows the increase in food demand till 2040, and again you see here Asian countries and African countries, the food demand will be higher, and obviously, one major reason in Asian countries is the population because the population is increasing; the population is more in Asia and Africa, so the food demand obviously will be more.

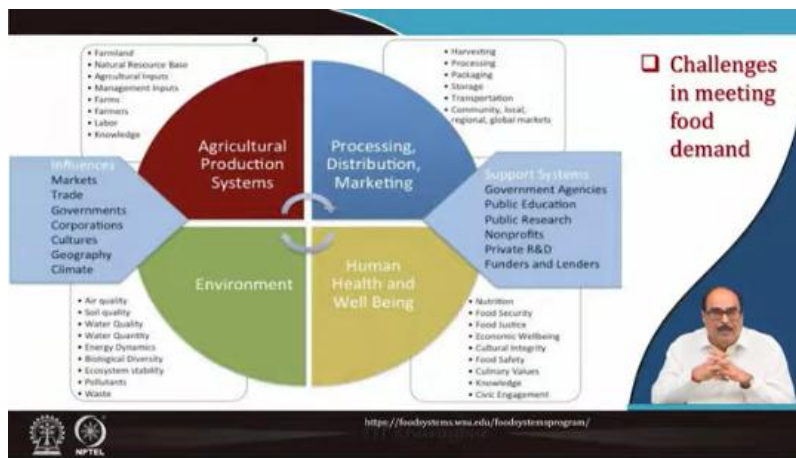

So, these are big challenges in meeting the food demand. Population growth is escalating food demand and exerting pressure on agricultural systems to scale up. Climate change is another problem. It poses a substantial threat to food production, affecting crop yield and distribution. Water scarcity limits the availability of water for irrigation and complicates food production systems.

Continuous agricultural expansion, coupled with poor land management practices, leads to soil erosion and land degradation, diminishing arable land and reducing its productivity. Increasing global demand for food leads to intensified competition for natural resources such as land and energy. This competition can hinder agricultural expansion and affect food prices and availability. Global food supply chains are often complex and prone to

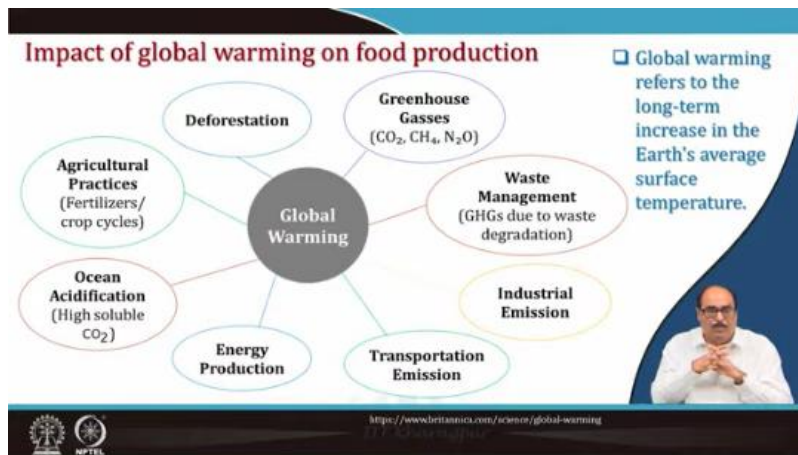

disruption, whether from geographical or geopolitical conflicts. Pandemics are natural disasters. Economic disparities affect food distribution and access, meaning that even with increased production, many people are still facing food insecurity, and the reasons for that are many. So, addressing these inequalities is vital in achieving food security for all.

Here, challenges face by the agricultural food system in meeting the food demand. So, we have to focus on the agricultural production systems. These are influenced by factors such as the environment, Processing, distribution, marketing, and human health and well-being. These are the four pillars.

We have to properly manage all these four issues that influence farmland, natural resources, agricultural various things, or even air quality, soil quality, water quality, etc. All these influence the agricultural production system as well as the environment, and these also influence the market, trade, government, corporations, cultures; and similarly, the support system is influenced by various processing, distribution, and marketing practices like harvesting, processing, packaging, etc. They all influence human health and well-being like nutrition, food security, food justice, and economic well-being. So, all these are interrelated, and one has to tackle them.

So, see the impact of global warming on food production. I already talked about global warming, and nowadays, in almost all scientific gatherings, whether it is G20, G8, or all those things, this issue is one of the major concerns.

Global warming refers to the long-term increase in the Earth's average surface temperature. And what are the various causes of global warming? That is deforestation, Greenhouse gas emissions, increase in greenhouse gas emissions, even waste management, and waste management, that is, there are greenhouse gases, a major proportion of this is contributed by waste degradation, industrial emissions, transportation emissions, energy production, even ocean acidification because of the highly soluble carbon dioxide, agricultural practices, excessive use of fertilizers, crop cycles, etc. These are the various contributors to global warming and therefore they influence agricultural cultivation.

So, climate change and agriculture, if you look at, an increase in temperature increases many diseases in crops, etc. 16 to 20 percent of the yield of major crops, such as corn, soybean, etc., is reduced even by a 1° Celsius temperature increase, which decreases the yield of major crops by up to 20 percent. If proper care is not taken by the 2080s, there could be about a 16 percent decrease in agricultural productivity. This can be observed due to climate change.

So, adaptation and mitigation challenges include increased input costs, risks to small farmers, soil degradation, pests, and diseases, such as the expansion of pest habitats, increased pest activities, and affected crop yields, including heat stress, drought, water scarcity, and changing growing seasons, etc. Even now, the growing seasons, harvesting seasons, and planting times, are affected by global temperature changes, so in fact, the entire agricultural system needs to be reworked. Agricultural scientists and engineers are being forced to rework their production strategies, etc. So, food supply chain disruptions, weather extremes, price volatility, and influences on food quality and nutrition, like nutrient depletion, are occurring as well as changes in crop composition and all those things. So, these are because all these climate changes affect all these activities in agriculture.

Impact on livestock and fisheries

- Global warming (rising temperatures, changing precipitation patterns, and ocean acidification) profoundly impacts livestock and fisheries.
- 5°C increase in temperature may lead to a 10% decrease in livestock yields across cow-calf and dairy operations.
- Conception rates could decline by 4.6% for every unit increase in the temperature-humidity index (THI) above 70.
- Global fish community biomass could decline by as much as 30% by 2100 due to global warming.
- The aquaculture is also said to be affected by ocean acidification, salt alteration, ocean intrusion in fresh water systems due to sea level increment.

<https://www.cifl.org/external/pubs/06/finald/2009/03/pdfl/cline.pdf>

UPT

Also, there is a significant impact on livestock and fisheries. Global warming, like rising temperatures, changing precipitation patterns, and ocean acidification, profoundly impacts livestock and fisheries. A 5° Celsius increase in temperature may lead to a 10% decrease in livestock yield across cow-calf and dairy operations. Conception rates could decline by 4.6% for every unit increase in temperature-humidity index above 70. Global fish community biomass could decline by as much as 30% by 2100 due to global warming. Aquaculture is also said to be affected by ocean acidification, salt alteration, and ocean intrusion into freshwater systems due to sea level rise.

So, globally, to combat the detrimental effect of global warming in food production, like obviously one has to go through the three major pillars in this area: the use of more and more climate-smart agriculture, conservation agriculture, improved irrigation practices, and crop diversification. Then, sustainable practices like reducing greenhouse gas emissions from food production including sustainable livestock practices, agroforestry,

□ Combat global warming in food production

Conservation agriculture, improved irrigation practices, & crop diversification

Reduce greenhouse gas emissions from food production, including sustainable livestock practices, agroforestry, & reduced food waste

Climate-Smart Agriculture

Sustainable Practices

Technological Innovation

Research into drought-resistant & heat-tolerant crop varieties is critical to ensuring future food security in a warming world

NPTEL

and reduced food waste. Then another very important area is technological innovations. Research into drought-resistant and heat-tolerant crop varieties is critical in ensuring future food security in a warming world. So, you have to have crop varieties which can withstand, and grow well even in high-temperature conditions.

So, limited resource management for food production, then, like these limited resource management encompasses practices and strategies aimed at maximizing agricultural productivity while conserving natural resources. Land, water, energy, and fertilizers are the most critical resources that need to be managed for food production.

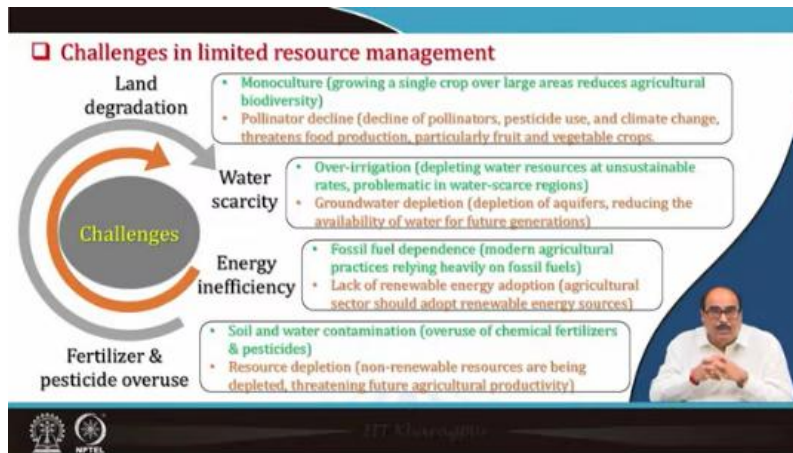

□ Limited resource management for food production

- Limited resource management encompasses practices and strategies aimed at maximizing agricultural productivity while conserving natural resources.
- Land, water, energy and fertilizer are most critical resources that need to be managed for food production.
- The land area usually increases with the practices such as deforestation which is damaging to the environment.
- Current practices followed in agriculture are not sustainable.
- Integration of the technologies can pose a possible sustainable solution.
- Global policy shift are essential for technological innovation and implementation.
- The Paris Agreement is international treaty on climate change that was enforced in 2016 to restrict global warming by 2 °C (3.6 °F) above pre-industrial levels.

NPTEL

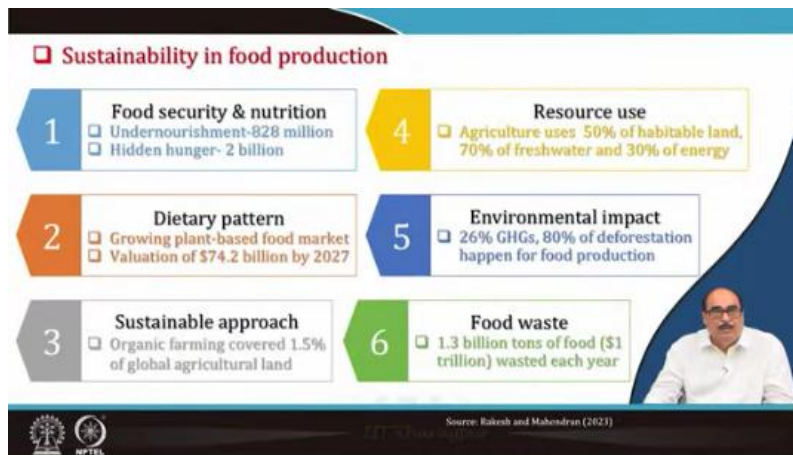

The land area usually increases with practices such as deforestation, which is damaging to the environment. Current practices followed in agriculture are not very sustainable. We have to do a lot in this area. Integration of technologies can pose a challenge or it can pose a possible sustainable solution. So various technologies have to be integrated at the farm level particularly for irrigation, sowing, harvesting and other practices like fertilizer application practices, etc. In all this, one has to use modern technologies, and these

technologies, if they are integrated properly, we can see a better future, or it may provide a possibly sustainable solution. Global policy shifts are essential for technological innovations and implementation. The Paris Agreement is an international treaty on climate change that was enforced in 2016 to restrict global warming by 2 degrees Celsius above pre-industrial levels. So, it has to be properly implemented.

So now the challenges in limited resource management are the ones that are land degradation like monoculture, that growing a single crop over large areas reduces agricultural bio-diversity, even pollinator decline, like the decline of pollinators, pesticide use, climate change, threatens food production, particularly fruits and vegetable crops. Then water scarcity, over-irrigation, depleting water resources at unsustainable rates, problematic water-scarce regions, or groundwater depletion, like the depletion of aquifers, reducing the availability of water for future generations. Energy efficiency is another challenge in resource management due to fossil fuel dependence. Modern agricultural practices rely heavily on fossil fuels, and there is a lack of renewable energy adoption. For example, the agricultural sector could adopt renewable energy resources. And finally, the overuse of fertilizers and pesticides. Soil and water contamination, along with the overuse of chemical fertilizers and pesticides, are major factors. Resource depletion, such as the depletion of non-renewable sources, threatens future agricultural productivity. So, considering all of these, our focus of agriculture has to be on how to overcome the problems of land degradation, water scarcity, energy inefficiency, and the overuse of fertilizers and pesticides.

So, to achieve sustainability in food production, there are again six major verticals,

such as food security and nutrition. You have to save food, grow more food, and reduce post-harvest losses, etc. Like dietary patterns, even the growing plant-based food market and the valuation of this \$74.2 billion by 2027 for plant-based products. Then, a sustainable approach is necessary, such as organic farming, etc. It covers 1.5% of global agricultural land. Then, in terms of resource use, agriculture uses 50% of habitable land, 70% of freshwater, and 30% of energy. Environmental impact: for example, about 26% of greenhouse gas emissions come from agriculture and food-related businesses, 80% of deforestation happens for food production. And then, food waste—again, 1.3 billion tons of food, costing around 1 trillion dollars, is wasted every year. That in fact, if we want to have sustainability in the food production system, we have to properly address all these issues and challenges.

Then, obviously, the strategies for improved resource management includes number one, land and soil: precision agriculture, biotechnology, and soil health are key. In water: one has to go for smart irrigation, sustainable practice integration. Remote sensing, drone robotics, automation, telemetry, and fleet management are key in the energy sector. And

then, finally, fertilizers and nutrient management: data analytics and decision support systems, precision agriculture should be used for managing fertilizers and nutrients in crops. So, these are the strategies to improve resource management in agriculture.

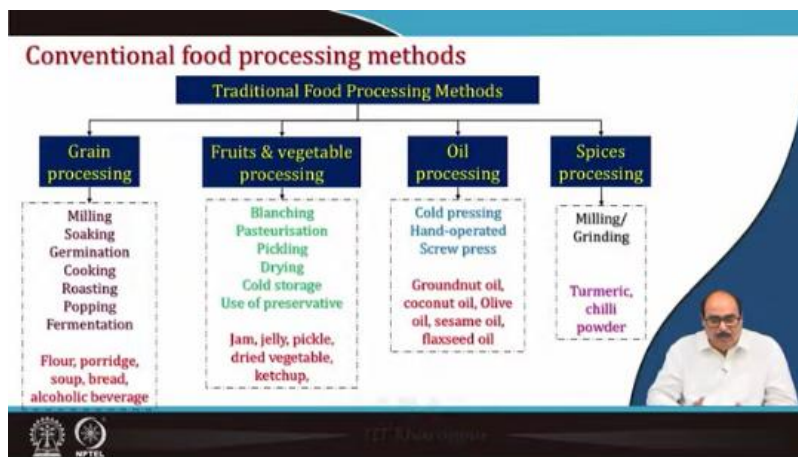

Food security—again, what is food security? It refers to the availability, access, and utilization of food that meets dietary needs and food preferences for an active and healthy life. And it is a very important activity for every nation, even to provide food to every person. Every person is important for a country, and that is why we should secure our food. So, food security—now we are talking about nutrition security or health security. So, for food security, there are four verticals again: availability, utilization, access, and stability. Availability means the supply of food influenced by local production, imports, and food reserves and for this whatever needs to be done should be done to make food available to people. And then, once food is made available to people, their aspect is important. Their aspect is its utilization, meaning to obtain sufficient food influenced by economic access and physical access as well. That is, everybody's food may be available, but everybody cannot buy it. Everybody cannot use it, cannot get it. So that disparity and all those things are required to be economic disparity and other things should be removed. Then access, similarly again, proper use of food involves knowledge and means to prepare nutritious meals using these raw food materials, etc. How should they be processed? How should they be cooked? So that the nutrition, etc. is maintained in food. Food security is also related to nutrition security. So that type of knowledge should be given to the people. People should be equipped with all the understanding about food and how to make it safe, and then obviously stability means food security over time, even in the face of economic, climatic, or political challenges. So, it should be stable. Everybody should be assured of food security.

So, in this slide, we have given an overview that is food waste and loss. what is that? It is one of the major factors which causes food insecurity. At one time, in many countries, people were not getting proper food, daily needed food, and at the same time, in some countries, a lot of food wastages, etc., are there. For instance, in the United Nations approximately 1.3 billion tons of food is wasted. Globally, food waste is around 30 percent, and the increase in greenhouse gas emissions is by 6 percent. This food waste

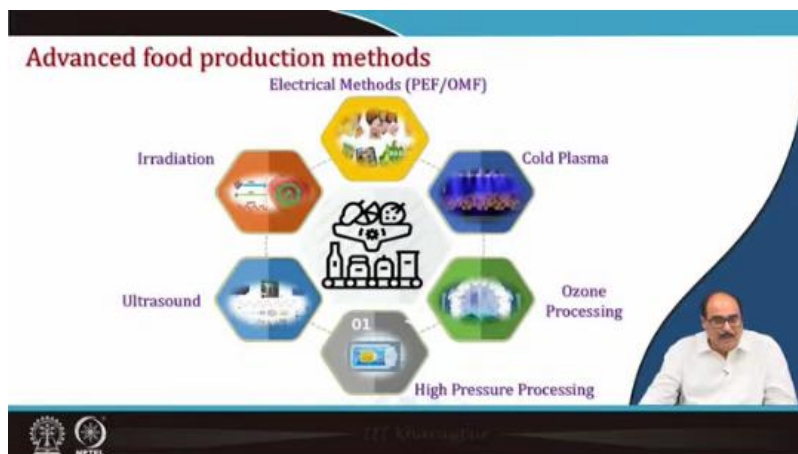

influences greenhouse gas emissions. So, food waste and food loss account for 6 to 10% of global greenhouse gas emissions, like 3.3 GT of CO₂ each year. So in this, you can see the crops that are consumed as food in China, India, USA, Indonesia, and Pakistan at the household level, at the food service level, as well as at the retail level. You can see that in all the countries, including India and China also, there is a significant, huge amount of food lost at all three levels, that is, the household level, food service level, as well as retail level. In this slide, it is the data in tons every year. If you look at the kg per capita per year, that is how much is the contribution of an individual person to the food losses, and here the condition you see in India, it is much lesser than in China per kg per capita per year, that is at the household level, the data is 64 the same data in India is 50, USA 59, Indonesia 77 and Pakistan 74 kg per capita per year, that is the contribution to food loss. similarly, if you see the retail sector also in India, it is the retail sector only, 16 kg per capita per person is there, whereas in China also 16 kg. So in almost all these countries, the retail sector food loss is almost similar. But yes, in the processing sector, again, India is the smallest. So, this obviously refers to India and China, because here, even the huge losses are present. That is the population. It can be related to the huge population in it. However, the per capita level losses are less in India.

Now, briefly, the conventional way these agricultural things can be made.

So, once you have tackled agricultural production, then you should use modern processing; there, one is the conventional food processing method and then the modern food processing method. Conventional, like traditional food processing methods in grain processing, include age-old technology like milling, soaking, germination, cooking, roasting, popping, fermentation, etc. to make products like flour, porridge, soup, beverages, alcoholic beverages, and so on. In fruits and vegetables, blanching, pasteurization, pickling, drying, cold storage, and use of preservatives have been the traditional technologies, and the products made traditionally include jam, jelly, pickles, dried vegetables, ketchup, and so on. In oil processing, cold pressing, hand-operated presses, screw presses, etc. are being used traditionally in the field like groundnuts, coconut oil, olive oil, sesame oil, flaxseed oil, etc. In spices, generally milling and grinding were used traditionally for turmeric, chilli, and powder.

Advanced food production methods, if you talk about them, there are electrical methods like pulse electric field or ohmic field, which is mostly the non-thermal processing like irradiation, ultrasound, use of ultrasound for processing, high-pressure processing, ozone

processing, and cold plasma. So, most of these technologies I have discussed in detail in my other course, that is, the novel technology of food processing and shelf life extension that is discussed. So, in this course, maybe in the later module, we will briefly tell the concept, but not the details.

Future trends in food production: if you look at this slide, there are major challenges. industries which are going more and more to meet the food demand, which is the major challenge. So, not only agriculture but other than agriculture as well. One such is lab-grown meat, which is one area for meat people to replace cattle growing, and for rearing cattle, etc., for meat purposes. It has been proven now that cattle rearing is one of the costlier technologies from the production as well as the environmental aspects. So, this can be, maybe in the future, you may say that cultured meat is produced and it has come in a big way. In cultured meat, as you can see here, it is produced by in vitro cultivation of animal cells; that is, animal cells are taken, and after the, instead of slaughtering the animals, the animal cells are taken, and these cells are inoculated into some sort of system. Then these cells grow in the laboratory. These grown cells are further put into the reaction medium or fermenters or whatever suitable reaction these meats can form. It is called cellular agriculture. It gives the oils, all these things, which are restored from the bioscience and look into pinkish products like muscle-like products that they grow in the reaction medium. They reorient, reorganize, etc., into a muscle-like material, which is finally, by using tissue engineering technologies, converted into exactly the product that mimics meat texture, even meat flavour, and all those things. So, there is a lot of work going on in several countries, including India, that is being done nowadays on lab-grown meat from cell to stick. Other technologies like artificial intelligence, machine learning, and robotics, etc., are coming. So, here it is 3D printing. 3D printing technology is another emerging technology that is likely to dominate the food production area and food processing area,

and 3D printing creates a three-dimensional object with the material being added together. You can even take synthetic ingredients, that is, chemical forms of ingredients and these ingredients can be properly blended and mixed, as you can see here in this picture. And then this is given a 3D, three-dimensional picture, created a digital class, digital gastronomy, to revolutionize food manufacturing with customized shape, colour, flavour, texture, and even nutrition. Sometimes this 3D printing can be used to provide customized nutrition or precise nutrition to the customers but food to the people. So, these are some of the areas where the future of food processing and food production can be seen. And apart from this, there are many other technologies. So, we will take the classes to come.

Qualitative losses in the food supply chain talk about there is nutritional quality, improper storage, transportation, and handling causing the loss of essential nutrients. Degradation of macronutrients exposed to high temperatures long storage time or degradation of protein content in grains and legumes all result in nutritional quality losses. Another is the physical quality of the food like damage to appearance during harvesting, handling, or transportation. Perishables such as fruits and vegetables lose their freshness and texture if they are not properly handled or if there is some cut or damage to the tissue. Then there may be taste and flavour degradation, poor storage or prolonged exposure to heat and light, which can degrade the taste and flavour. Also, the safety and hygiene, and it is very important if the supply chain is not properly maintained, like poor handling, unsanitary conditions are there, or even improper storage, etcetera, even if the food is exposed to pesticides. Pesticides, toxins, and other chemicals during production or storage, may seriously impair the safety and hygiene and then shelf life reduction of food products. Obviously, all these may result in the shelf life reduction of food products. light, oxygen, moisture, etcetera, are also important factors which influence the shelf life of the food materials. This supply chain must be properly maintained to manage all these things.

Prevention strategies for qualitative losses

- ❑ **Improved packaging**
 - ✓ Preserves food quality, such as modified atmosphere packaging, can extend shelf life and retain freshness of food products.
- ❑ **Consumer awareness**
 - ✓ Educating consumers on food storage, portion planning, and the understanding them the meaning of "use by" dates can reduce waste at the household levels.
- ❑ **Sanitary handling practices**
 - ✓ Encouraging proper hygiene and handling practices throughout the supply chain reduces the risk of contamination and spoilage.

NPTEL

Prevention strategies for qualitative losses during the supply chain, during processing, and all related aspects. Obviously, improved packaging should be considered, as proper packaging preserves food quality. Such as modified atmosphere packaging, which can extend shelf life and retain the freshness of the food products. Consumer awareness is very important; educating consumers on food storage, portion planning, and understanding labels, such as use-by dates, can reduce waste at the household level. These should be properly taught: What is the use-by date, and by which date it should be consumed? Sanitary handling practices are very important. Encouraging proper hygiene and handling practices throughout the supply chain can reduce the risk of contamination and spoilage.

Quantitative losses in food supply chain

- ❑ **Production stage**
 - Pre harvest losses - Poor crop management, pests, and diseases
 - Harvesting losses - Improper harvesting techniques or timing
- ❑ **Post harvest & storage**
 - Inappropriate storage conditions
 - Insect infestation & microbial contamination
- ❑ **Processing & packaging**
 - During processing (peeling, trimming, milling or processing of grains)
 - Improper packaging can result in physical damage or contamination
- ❑ **Retail & consumers**
 - Waste at the household level, lack of storage facilities
 - Food is often discarded due to overstocking, damage, or nearing expiration dates
- ❑ **Distribution & transportation**
 - Poor handling, rough transport conditions

NPTEL

Then, qualitative loss in the food supply chain can occur at the production stage, such as pre-harvest losses, harvesting stages, pre-harvest proper crop management, pest management, disease management, or post-harvest improper handling, etc., improper harvesting techniques or timings, etc., can reduce quality, but proper care should be taken to reduce these losses at this stage. Then, post-harvest and storage. If there are inappropriate storage conditions, insect infestation, or microbial contamination, that will result in huge

losses. So, it has to be taken care of and properly managed. Then processing and packaging like peeling, trimming, milling, or processing of grains or even improper packaging can result in physical damage or contamination, etc. Then in the retail and consumer waste at the household level due to lack of storage facilities, food is often discarded due to overstocking, damage, or nearing expiration dates. In the distribution and transportation, poor handling, rough transport conditions, etc. can result in more losses. So, this should be properly managed.

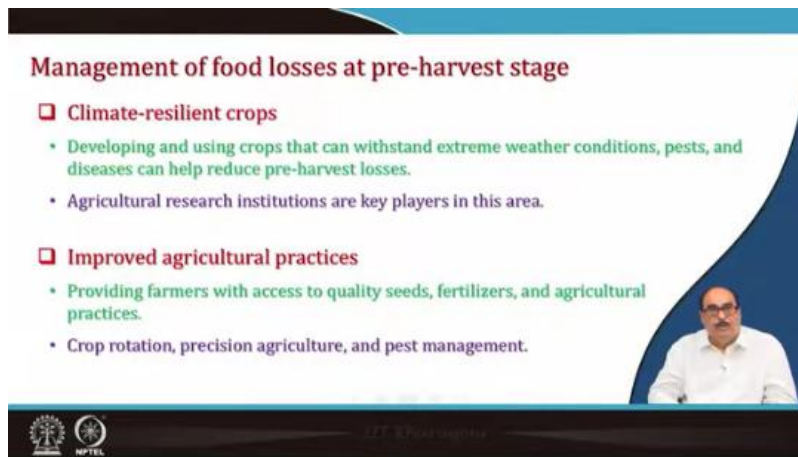

Prevention strategies for quantitative losses

- **Improved harvesting techniques**
 - ✓ Training farmers in better harvesting practices can reduce field losses.
- **Enhanced storage solutions**
 - ✓ Utilizing hermetic storage, silos, and cold chain infrastructure helps reduce post-harvest losses.
- **Efficient transportation**
 - ✓ Improving logistics and using temperature-controlled transport can significantly reduce spoilage during distribution.
- **Better market management**
 - ✓ Establishing systems that allow surplus food from retailers and markets to be redistributed can prevent food from being wasted.

The slide features a blue and white color scheme. In the bottom right corner, there is a small video inset showing a man with glasses and a white shirt. The bottom of the slide contains logos for 'APJKTU' and 'NPTEL' on the left, and the text 'Dr. K. S. Narayana' in the center.

Then prevention strategies for qualitative losses. Moreover, you have to take lessons from what are the various reasons for the quantitative losses. One has to know what are the factors, So, that those should be controlled. One is improved harvesting techniques. The farmer should be properly trained for better harvesting practices, and this can reduce the field losses. Enhanced storage conditions like utilizing hermetic storage, silos and cold chain infrastructure. It helps reduce post-harvest losses. Efficient transportation like improving logistics and using temperature-controlled transport can significantly reduce spoilage during distribution, particularly for perishables, etc. Temperature-controlled transportation can help significantly in reducing the losses and enable better market management. Establishing systems that allow surplus food from retailers and markets to be redistributed can prevent food from being wasted. It should be properly managed at the retailer level.

Management of food losses at the pre-harvest stage.

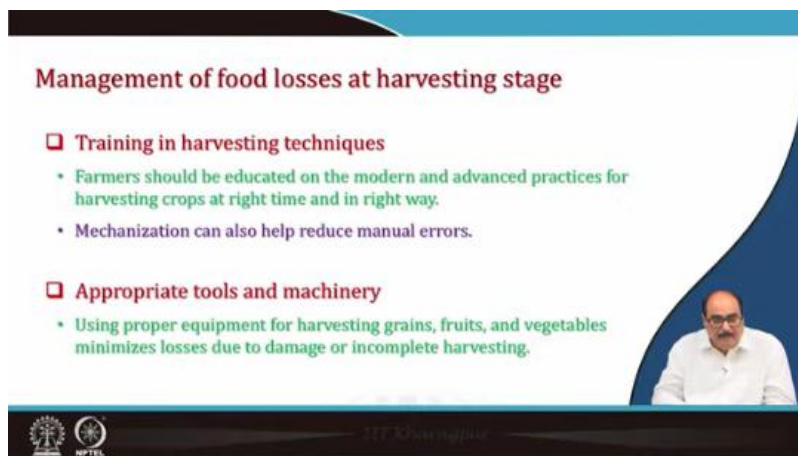

Management of food losses at pre-harvest stage

- ❑ **Climate-resilient crops**
 - Developing and using crops that can withstand extreme weather conditions, pests, and diseases can help reduce pre-harvest losses.
 - Agricultural research institutions are key players in this area.
- ❑ **Improved agricultural practices**
 - Providing farmers with access to quality seeds, fertilizers, and agricultural practices.
 - Crop rotation, precision agriculture, and pest management.

Dr. K. Srinivasan

Number one, climate-resilient crops: developing and using crops that can withstand extreme weather conditions, pests, and diseases can help reduce pre-harvest losses. Also, agricultural research institutions are key players in this area. New technologies should be developed, new machinery should be developed, and these can be used for climate-resilient agriculture. Additionally, improved agricultural practices, such as providing farmers with access to quality seeds, quality fertilizers, and agricultural practices. These would include the advantages of crop rotation, precision agriculture, and pest management.

Management of food losses at harvesting stage

- ❑ **Training in harvesting techniques**
 - Farmers should be educated on the modern and advanced practices for harvesting crops at right time and in right way.
 - Mechanization can also help reduce manual errors.
- ❑ **Appropriate tools and machinery**
 - Using proper equipment for harvesting grains, fruits, and vegetables minimizes losses due to damage or incomplete harvesting.

Dr. K. Srinivasan

Then, the management of food losses at the harvesting stage. Training farmers in harvesting technologies: they should be educated on the use of modern and advanced practices for harvesting crops at the right time and in the right way. Mechanization can also help reduce manual errors, etc. So, more and more mechanized harvesting practices should be developed and implemented. Appropriate tools and machinery, using proper equipment for harvesting grains, fruits, vegetables, will minimize losses due to damage or incomplete harvesting.

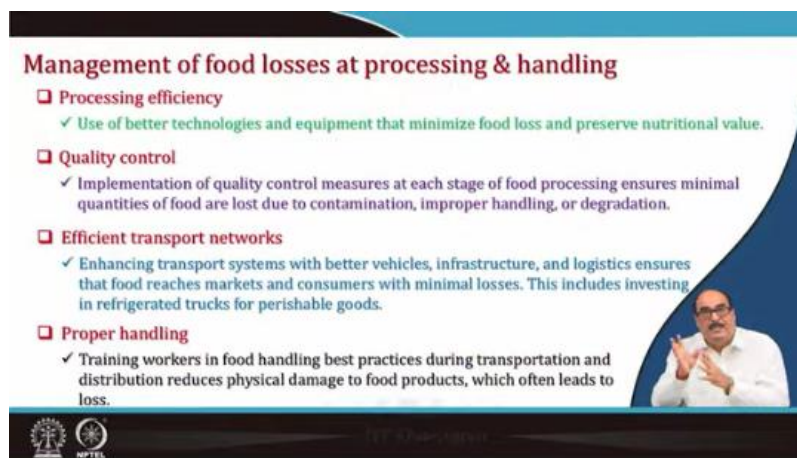

Management of food losses at post-harvesting stage

- ❑ **Storage solutions**
 - Developing proper storage facilities, such as hermetic storage for grains or temperature-controlled environments for perishables, can prevent spoilage due to moisture, pests, or fungal infections.
- ❑ **Improved packaging**
 - Better packaging solutions, such as vacuum packing or modified atmosphere packaging, can extend the shelf life of perishable items and reduce spoilage.
- ❑ **Cold chain infrastructure**
 - Establishing a reliable cold chain network for the storage and transportation of temperature-sensitive food products can drastically reduce spoilage during transit.

Then, the management of food losses at the post-harvest stage, like storage solutions and developing proper storage facilities like hermetic storage for grains or temperature-controlled environments for perishables, can prevent spoilage due to reduced moisture, pests, or fungal infections. Improved packaging: better packaging solutions such as vacuum packaging or modified atmosphere packaging, can extend the shelf life of perishable items and reduce their spoilage. Cold chain infrastructure, like establishing a reliable cold chain network for the storage and transportation of temperature-sensitive food products can drastically reduce spoilage during transit.

Then, even at the processing and handling level what are the strategies for the management of food losses?

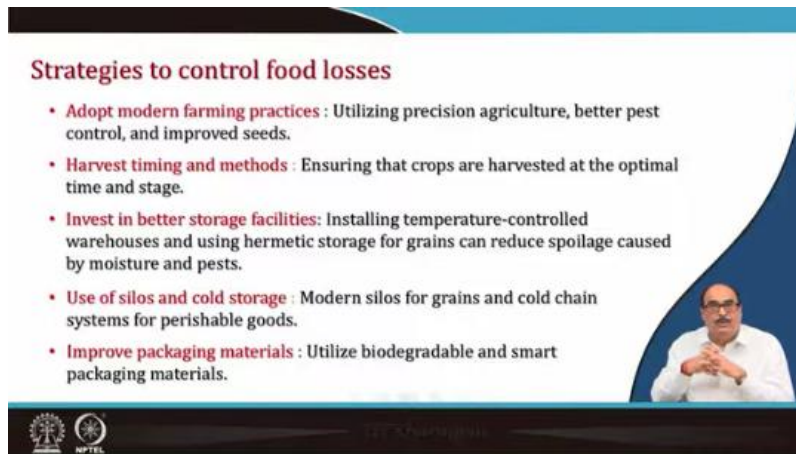

Management of food losses at processing & handling

- ❑ **Processing efficiency**
 - ✓ Use of better technologies and equipment that minimize food loss and preserve nutritional value.
- ❑ **Quality control**
 - ✓ Implementation of quality control measures at each stage of food processing ensures minimal quantities of food are lost due to contamination, improper handling, or degradation.
- ❑ **Efficient transport networks**
 - ✓ Enhancing transport systems with better vehicles, infrastructure, and logistics ensures that food reaches markets and consumers with minimal losses. This includes investing in refrigerated trucks for perishable goods.
- ❑ **Proper handling**
 - ✓ Training workers in food handling best practices during transportation and distribution reduces physical damage to food products, which often leads to loss.

Obviously, processing efficiency and the use of better technologies, maybe advanced technologies, modern technology, and equipment, can minimize food losses and preserve nutritional value. Then, the implementation of quality control measures at various stages of food processing ensures minimal quantities of food are lost due to contamination,

improper handling, or degradation. And then, as earlier also told, efficient transport networks. Enhancing the transport system with better vehicles, infrastructure, and logistics ensures that the food reaches the market and consumers with minimal losses and this includes investing in refrigerated trucks for perishable goods. Proper handling, training workers in food handling, and best practices during transportation and distribution. It will reduce physical damage to the food products, which often leads to losses.

Strategies to control food losses

- **Adopt modern farming practices** : Utilizing precision agriculture, better pest control, and improved seeds.
- **Harvest timing and methods** : Ensuring that crops are harvested at the optimal time and stage.
- **Invest in better storage facilities**: Installing temperature-controlled warehouses and using hermetic storage for grains can reduce spoilage caused by moisture and pests.
- **Use of silos and cold storage** : Modern silos for grains and cold chain systems for perishable goods.
- **Improve packaging materials** : Utilize biodegradable and smart packaging materials.

The slide features a blue and white color scheme with a curved design on the right side. A small video inset in the bottom right corner shows a man in a white shirt speaking. Logos for ANILAM and NPTEL are visible in the bottom left corner.

So, overall, you can say that strategies to control food losses include adopting modern farm practices like utilizing precision agriculture, better pest control, utilization of improved seeds, proper harvest timings and methods, like ensuring that the crops are harvested at the optimal time and stage. Invest in better storage facilities, like installing temperature-controlled warehouses and using hermetic storage for grains, can reduce spoilage caused by moisture and pests. Use of silos and cold storage, like modern silos for grain and cold chain systems for perishables, or improved packaging materials. Utilize biodegradable and smart packaging materials. So, these should be the strategies to control food losses.

Vacuum sealing and modified atmosphere packaging are another technology for a strategy to maintain the freshness of perishable foods. Efficiency in processing units is another very important aspect.

Strategies to control food losses

- **Vacuum sealing and modified atmosphere packaging (MAP)** : Maintain the freshness of perishables foods.
- **Efficiency in processing units** : Use of advanced processes in food manufacturing.
- **Training for workers** : Training workers in proper handling and processing techniques.
- **Optimize handling practices** : Educating workers in best practices for handling products.
- **Better demand forecasting** : Using AI and analytics to predict consumer demand accurately.

Dr. D.T. Khurragha

NPTEL

The use of advanced processes in food manufacturing, training of workers, optimizing handling practices and better demand forecasting using artificial intelligence and data analytics to predict consumer demand accurately can control food losses. Educating the workers on best practices for handling the products and training the workers in proper handling and processing techniques are other strategies to control food losses. So, these are some ways by which one can control food losses.

Summary

- The global population is expected to grow, increasing food demand by 35 to 56% by 2050, which puts significant pressure on agricultural systems to meet these needs.
- Critical resources like land, water, and energy are becoming limited, necessitating more efficient and sustainable farming practices to meet growing food demands.
- It is important to manage food losses at various stages—pre-harvest, harvesting, and post-harvest—through improved techniques and infrastructure to ensure food security.
- Advanced methods like high-pressure processing, 3D printing, and sustainable packaging are future trends to reduce waste and improve the efficiency of the food supply chain.

Dr. D.T. Khurragha

NPTEL

So, finally, I would like to summarize this lecture by saying that global production is expected to grow. Increasing food demand by 35 to 56% by 2050, which puts significant pressure on agricultural systems to meet these needs. Critical resources like land, water, and energy are becoming limited, necessitating more efficient and sustainable farming practices to meet growing food demands. It is important to manage food losses at various stages like pre-harvest, harvest, and post-harvest through improved techniques and infrastructure to ensure food security. Advanced methods like high-pressure processing, 3D printing, and sustainable packaging are the future trends to reduce waste and improve the efficiency of the food supply chain.

So, these are the references which are used in this lecture.
